Coil Designs for Real Magnets

Superconducting
Magnet Division

LHC Dipole

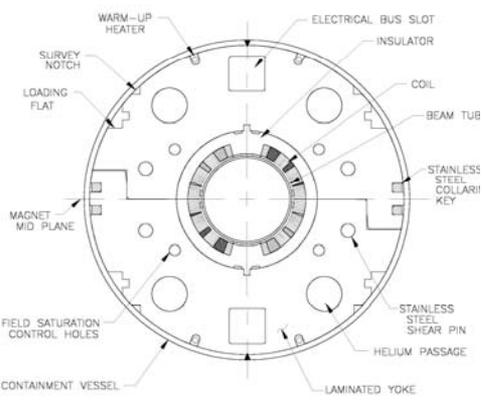

HERA Dipole

- All magnets use NbTi Superconductor
- All designs use cosine theta coil geometry

RHIC Dipole

Tevatron Dipole

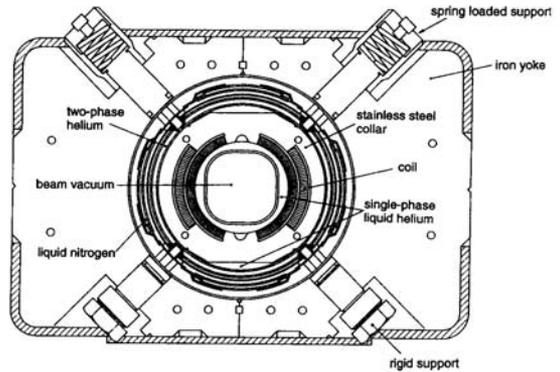

Figure 4.9: The Tevatron 'warm-iron' dipole (Tollestrup 1979).

Do they really look like having a cosine theta current distribution?

Or that matter, even an elliptical geometry for conductor having a constant current density?

Coil Cross-section Optimization (1)

The optimization of a coil cross-section for a good magnetic design involves:

- Minimizing field harmonics
- Maximizing field (Transfer Function) for a lower number of turns
- Minimizing Peak Field (Max. field on the conductor for given central field)

At first, it appears to be fairly straight forward process, thanks, in part, to the modern automated codes like ROXIE and PAR2DOPT, etc.,

In fact, one can built a magnet based on the optimized coil structure obtained by a relatively new user.

Coil Cross-section Optimization (2)

But the advanced cross-section optimization is a bit more involved:

- One must avoid designs that create mechanical difficulties
- One should look for flexibility to allow future adjustments
- Also look for special requirements in each application.

One approach fits all, may not always be a good strategy.

My Experience:

- The initial design, quite often sets, the eventual performance of the magnet apart from degree of difficulties in manufacturing the magnet.
- As compared to building magnets, design process takes a relatively small resources. Spend time in looking for as many possibilities/options as possible.

Field Harmonic Definitions

The field quality in magnets is expressed in terms of the normal and skew harmonic coefficients, b_n and a_n by the following expansion:

$$B_y + iB_x = 10^{-4} \times B_R \sum_{n=1}^{\infty} (b_n + ia_n) [(x + iy) / R]^{n-1}$$

where x and y are the horizontal and vertical coordinates, B_R is the field strength of the primary harmonics at the “reference radius” R . The values of the field harmonic are given in the units of 10^{-4} .

The definition used above (European convention) differs from that used in many U.S. publications (US convention), where $n-1$ is replaced by n and the summation starts from $n = 0$.

Field and Harmonics From A Current Block (No Iron)

Consider a “*Radial Block*” between radii ρ_1 & ρ_2 and angle ϕ_1 & ϕ_2 having a current density of J . The total current (I) and harmonics (A_n, B_n) are given by:

$$I = \frac{1}{2}J(\rho_2^2 - \rho_1^2)(\phi_2 - \phi_1)$$

$$A_1 = -\frac{\mu_o J}{2\pi}(\rho_2 - \rho_1)[\cos(\phi_2) - \cos(\phi_1)],$$

$$A_2 = -\frac{\mu_o J R_o}{2\pi} \ln\left(\frac{\rho_2}{\rho_1}\right)[\cos(2\phi_2) - \cos(2\phi_1)],$$

for $n \geq 3$

$$A_n = \frac{\mu_o J}{2\pi} \frac{R_o^{n-1}}{n(n-2)} \left(\frac{1}{\rho_2^{n-2}} - \frac{1}{\rho_1^{n-2}} \right) [\cos(n\phi_2) - \cos(n\phi_1)]$$

$$B_1 = -\frac{\mu_o J}{2\pi}(\rho_2 - \rho_1)[\sin(\phi_2) - \sin(\phi_1)],$$

$$B_2 = -\frac{\mu_o J R_o}{2\pi} \ln\left(\frac{\rho_2}{\rho_1}\right)[\sin(2\phi_2) - \sin(2\phi_1)],$$

for $n \geq 3$

$$B_n = \frac{\mu_o J}{2\pi} \sum_{n=3}^{\infty} \frac{R_o^{n-1}}{n(n-2)} \left(\frac{1}{\rho_2^{n-2}} - \frac{1}{\rho_1^{n-2}} \right) [\sin(n\phi_2) - \sin(n\phi_1)]$$

$n = 1$ refers to dipole.
 R_o is the reference radius.

See my thesis for these
and other derivations.

Homework Assignment (one block)

Assume that a current block is between radii 10 cm and 12 cm and it starts at an angle $\Phi = 0$.

Find the subtended angle (or the angle at which the block must end) for

- The normal sextupole harmonic to be zero. Is it a unique solution?
- Assume that you have a dipole symmetry. How many other blocks must be present to generate this symmetry (give number and angles).
- Compute the values of the first three non-zero allowed harmonics in Tesla (A_n and/or B_n) at a reference radius of 6 cm.
- Do the above for decapole harmonic to be zero. Is it a unique solution?
- Can you find a solution for which both sextupole and decapole harmonics are zero? The block does not have to start from an angle $\Phi = 0$.

What happens if it is in a cylindrical iron cavity having a permeability of (a) 10, (b) 100 and (c) 1000. **Hint: You can use the method of images.**

Homework Assignment (Two blocks)

Assume that there are two current blocks. First between radii 10 cm and 11 cm and second between 11 cm and 12 cm. Both starts at an angle $\Phi = 0$.

Find the subtended angle (the angle at which block must end) for the normal sextupole harmonic and decapole harmonics to be zero.

Is it a unique solution?

What happens if it is in a cylindrical iron cavity having a permeability of

- (a) 10
- (b) 100 and
- (b) 1,000.

Hint: You can use the method of images.

How to Look for Optimal X-section (1)

- 1. Look for designs that look similar to cosine theta distribution (experience)**
- 2. Use special techniques/software (artificial intelligence)**
- 3. Cover a large range of combinations and find the best**

My recommendation, go for the 3rd option (several thousand cases):

It does not take long to look a large number of possibilities - less than a few seconds per case if the peak field is not computed.

To save time compute peak field only in promising solutions.

How to Look for Optimal X-section (2)

Develop a front-end program to automatically create several cases for a series optimization run.

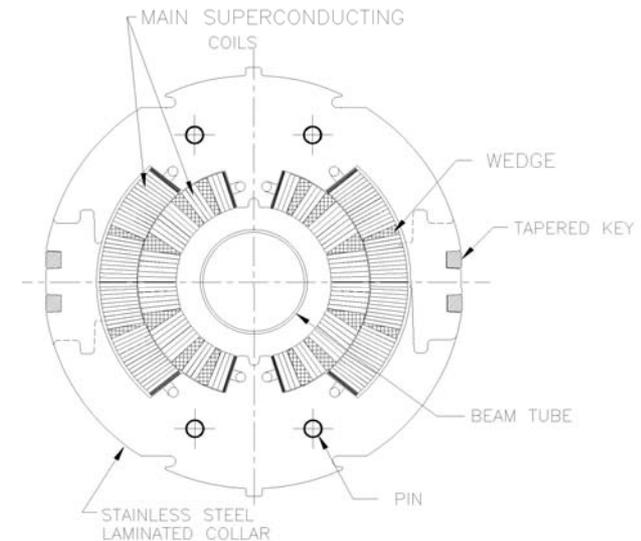

In this optimization:

- **Vary number of blocks and number of turn in those blocks.**
- **Vary starting condition of wedges, etc.**

Post-process results to select a limited cases with filters for harmonics, etc.

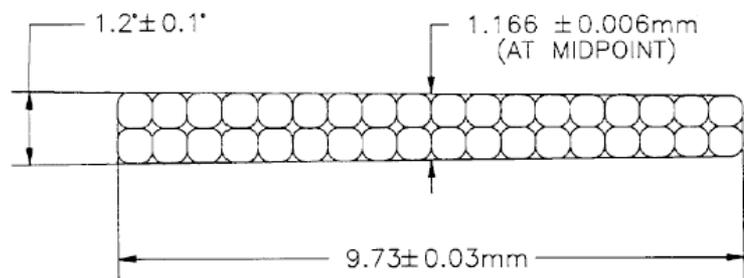

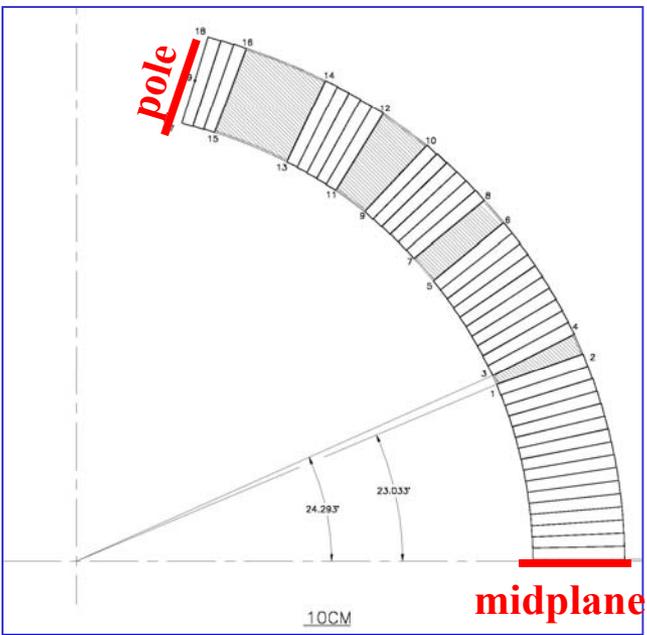

- **Compute peak field for these selected cases.**

Go back and carefully evaluate and further optimize these few cases for performance, mechanical layout, flexibility, sensitivity, efficiency and any other requirement.

An Example of Pre-processor for Generating Cases for a Series Run

A D07GEN Run

```

1 N1      19.00000  0.      1.      30.

Influence of Coil Parameters in SSC 50 mm Aperture Dipole

Note the order of magnitude of change in harmonics by a 25 micron change in dimension.

Table 4.3.1: The effect of a $+25\mu\text{m}$ change in a wedge thickness or pole width on the transfer function and the field harmonics in the SSC 50 mm aperture dipole magnet. The field harmonics are calculated with a 10 mm reference radius. The numbering of the wedges is counter-clockwise from the midplane. The pole width is measured from the vertical axis.

| Parameter changed | δTF $10^{-4} \frac{T}{kA}$ | δb_2 10^{-4} | δb_4 10^{-4} | δb_6 10^{-4} |
|----------------------|---------------------------------------|---------------------------|---------------------------|---------------------------|
| Wedge No. 1 | -0.78 | -0.24 | 0.01 | 0.005 |
| Wedge No. 2 | 0.42 | 0.30 | 0.03 | -0.005 |
| Wedge No. 3 | 1.16 | 0.36 | -0.02 | 0.00 |
| Wedge No. 4 | -0.29 | -0.06 | 0.00 | 0.00 |
| Pole Width (inner) | 2.0 | 0.23 | -0.03 | 0.005 |
| Pole Width (outer) | 1.13 | 0.21 | 0.00 | 0.000 |

Wedge No. 4 is in outer layer.

Influence of Coil Parameters in RHIC 80 mm Aperture Dipole

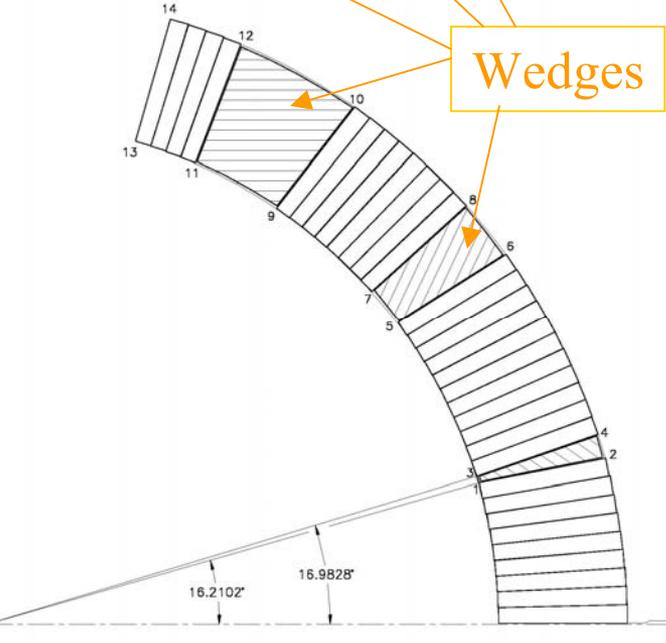

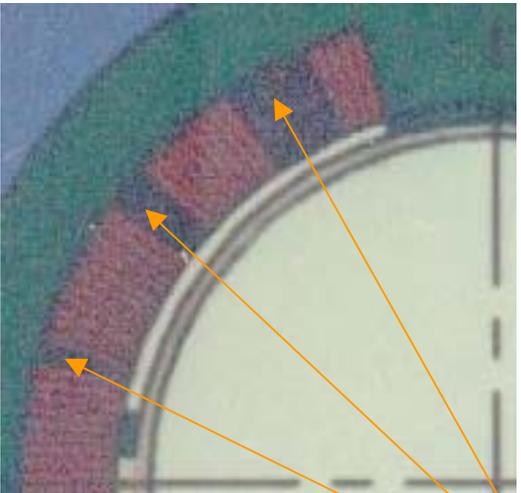

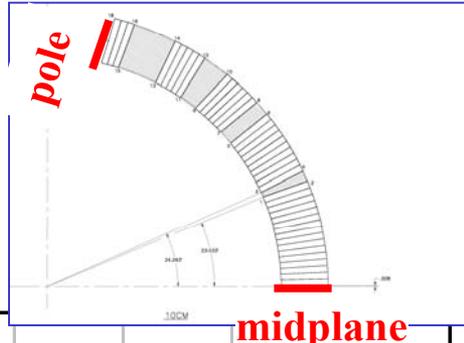

Table 4.3.2: The computed change in the transfer function and field harmonics produced by a $+25\mu\text{m}$ ($0.001''$) change in the wedge thickness, pole width or midplane gap in the RHIC 80 mm aperture arc dipoles. The field harmonics are calculated with a 25 mm reference radius. The numbering of the wedges starts at the midplane. The pole width and midplane gap are measured from the vertical and horizontal axis, respectively.

| Parameter | δTF | δb_2 | δb_4 | δb_6 | δb_8 |
|--------------|------------------------|--------------|--------------|--------------|--------------|
| changed | $10^{-4} \frac{T}{kA}$ | 10^{-4} | 10^{-4} | 10^{-4} | 10^{-4} |
| Wedge 1 | -0.6 | -0.98 | -0.122 | 0.061 | 0.043 |
| Wedge 2 | 0.1 | 0.69 | 0.423 | 0.022 | -0.050 |
| Wedge 3 | 1.1 | 1.42 | -0.090 | -0.068 | 0.041 |
| Pole Width | 1.7 | 1.11 | -0.154 | 0.039 | -0.014 |
| Midplane Gap | -0.9 | -1.68 | -0.557 | -0.156 | -0.050 |

Notice that the magnitude of change in harmonics by a 25μ change, is much large in RHIC dipole than in SSC dipole. WHY?

Change in Harmonics for 0.1 mm Change in Dimension in D0 Dipole

RHIC Insertion Dipole D0 with single layer coil
Coil inner radius = 100 mm,
Harmonic reference radius = 65 mm

A Flexible Design from the Beginning

Design Philosophy:

- Start out a design from the beginning itself, that allows significant adjustability for field harmonics and mechanical parameters (cable thickness, wedges, etc.).
- A flexible design is generally economical, efficient and produces magnets with better performance. I think it's a prudent approach.

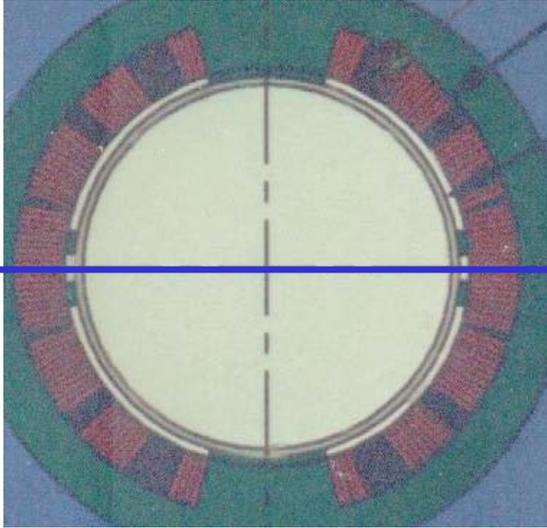

Geometric: Start with a larger than required shim and midplane cap. Then adjust it, as required without changing the cross-section of the cured coil. One can also adjust the layers of wedge/cable insulation, if needed. These three parameters can adjust, first two allowed harmonics and pre-stress or cable insulation. This approach was used extensively in various RHIC magnets.

Saturation: Start out with holes and fill them with iron rods. Or, punch holes in laminations later.

In KEK, C.F. dipole, one may consider adjusting for quad and sextupole component.

Change in Midplane Gap to Adjust Harmonics

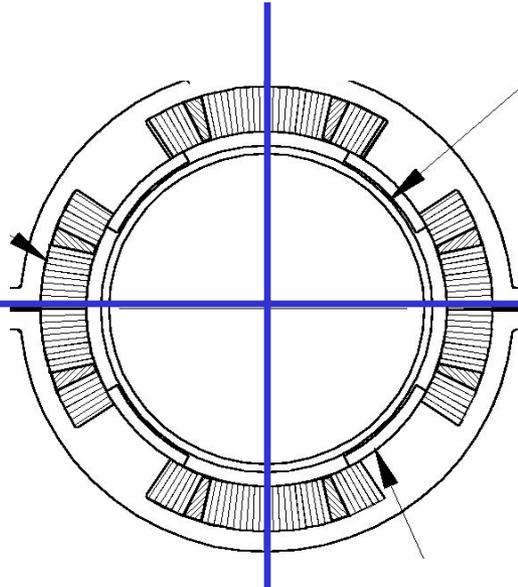

(can be easily done by changing the size of the ground-plane insulation cap)

Coil-to-coil
midplane gap
(1 in dipole)

Table 4.4.1: The computed and measured change in field harmonics at 25 mm reference radius due to a change in the coil midplane gap. The midplane gap was increased from 0.114 mm to 0.16 mm in the rebuilt 80 mm aperture RHIC model dipole magnet DRS009. In the production magnets, the midplane gap was changed back to 0.114 mm from 0.16 mm to adjust the b_4 harmonic.

| | Δb_2 | Δb_4 | Δb_6 | Δb_8 |

Stored Energy and Inductance Calculations

The stored energy and the inductance are related through the following formula :

$$\text{Stored Energy} = \frac{1}{2} \text{Inductance} \times (\text{Current})^2.$$

The inductance decreases at high field as the iron yoke saturates.

The results of POISSON computations for the SSC 50 mm aperture dipole are given at 6.5 kA in Table 6.2.9 for the stored energy per unit length and the inductance per unit length. The total stored energy and the inductance for a 15 m long dipole are also given.

Table 6.2.9: Stored Energy and Inductance at 6.5 kA as computed with the code POISSON for the SSC 50 mm aperture dipole.

2-d Modeling program compute stored energy. Don't forget to multiply by the program symmetry.

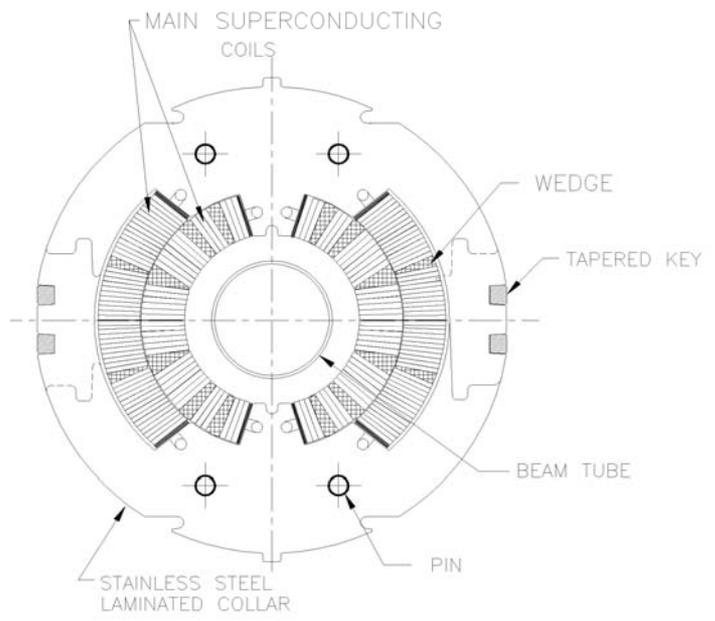

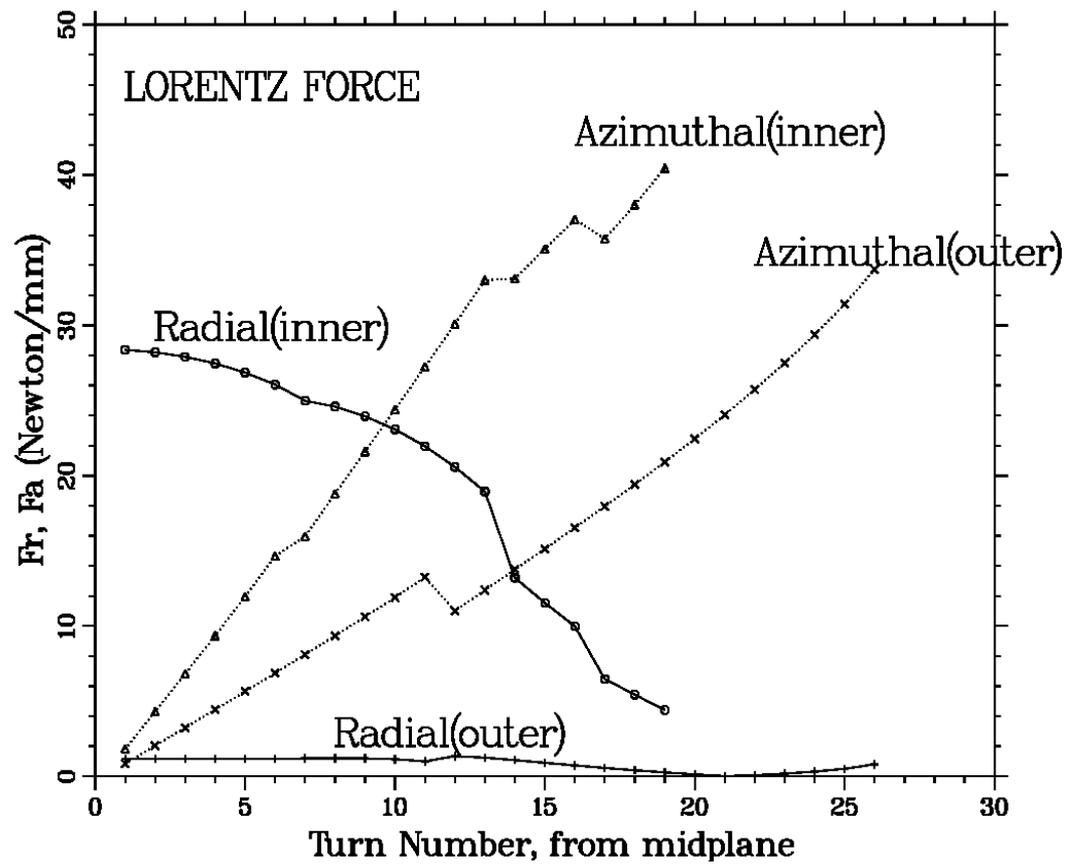

| | |
|--|--------|
| Stored Energy per unit length, kJ/m | 105.0 |
| Stored Energy for 15 m long Dipole, kJ | 1575.6 |
| Inductance per unit length, mH/m | 4.972 |
| Inductance for 15 m long Dipole, mH | 74.585 |

Lorentz Forces on the Individual Turn of the SSC Dipole

Superconducting Magnet Division

Figure 6.2.5: The magnitude of the components of the Lorentz force on the individual turns in a SSC 50 mm prototype magnet. The radial component of the force (F_r) pushes the coil outward and the azimuthal component (F_a) compresses the coil towards the midplane (horizontal plane). There are 19 turns in the inner layer and 26 turns in the outer layer of each quadrant.

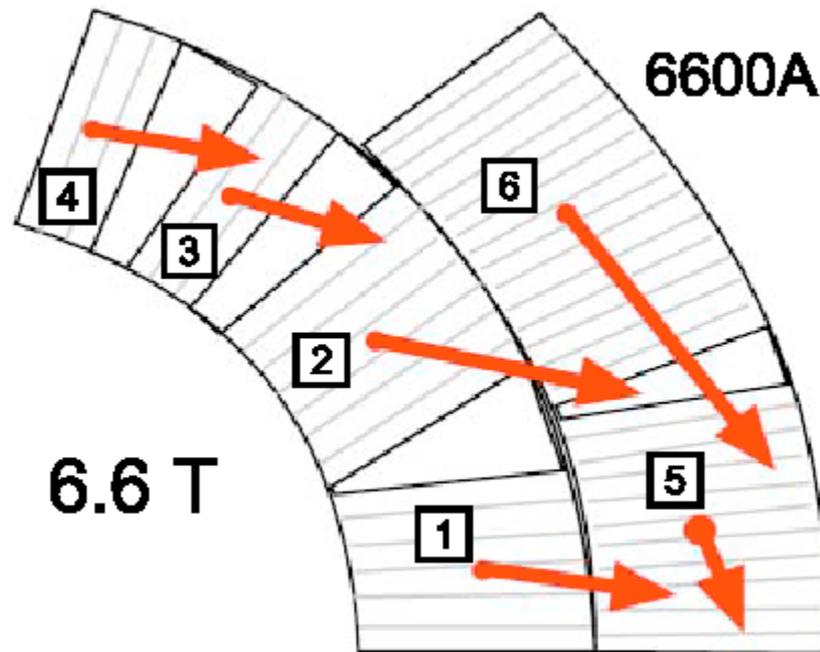

Computed Lorentz forces at the design field of 6.6 T (6.6 kA).

Forces in the Current Blocks of SSC Dipole

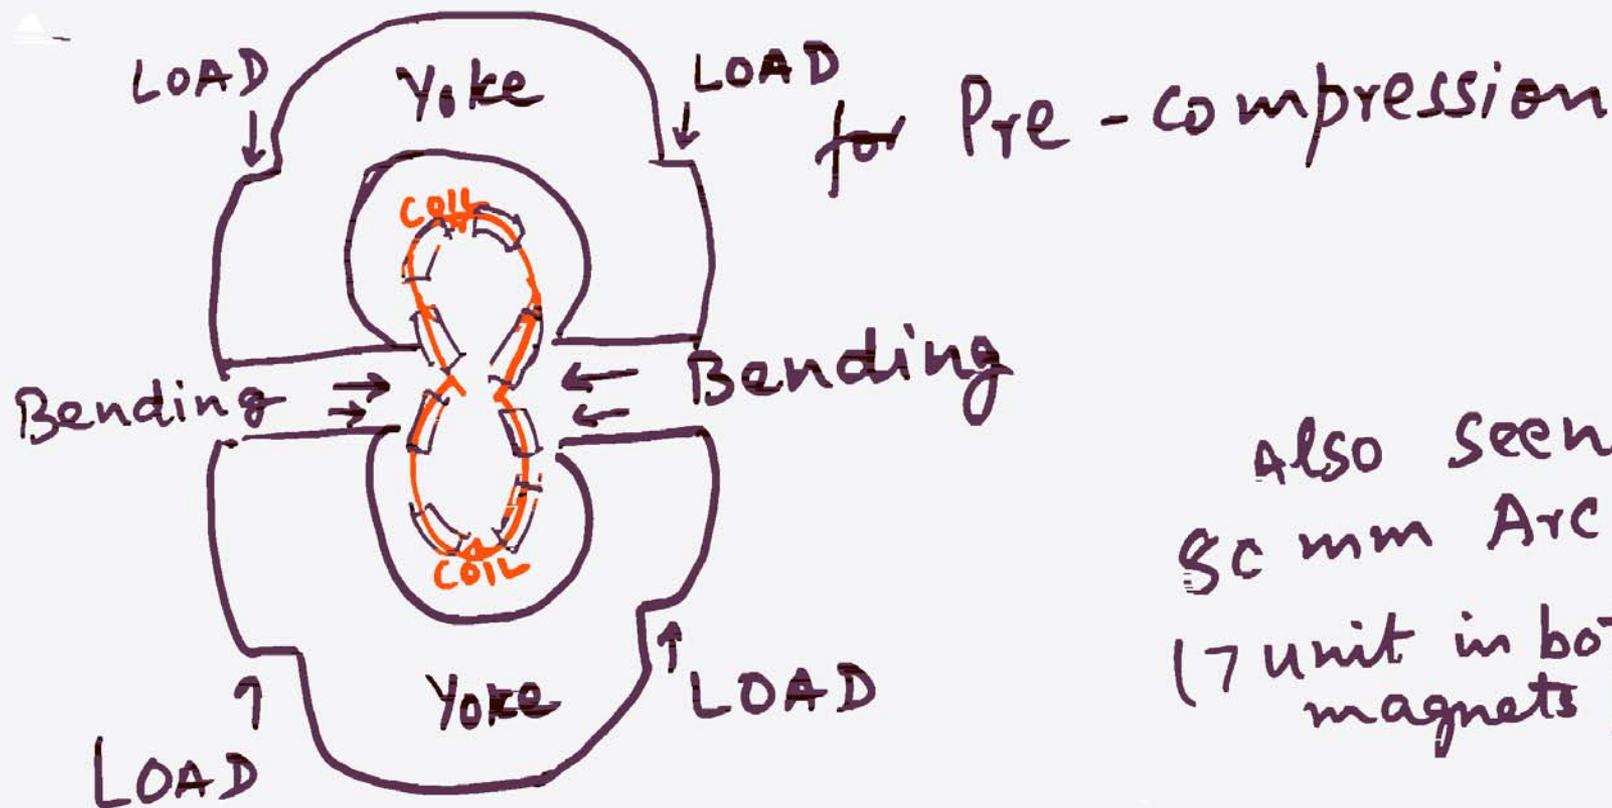

The table summarizes the forces on the blocks in the example SSC dipole.

| BLOCK | F_x , lb./in | F_y , lb./in | F_x , N/m | F_y , N/m |
|-------|----------------|----------------|-------------|-------------|
| 1 | 1005.46 | -108.98 | 1.76E+05 | -1.91E+04 |
| 2 | 1312.68 | -237.56 | 2.30E+05 | -4.16E+04 |

Octupole in Quadrupoles When Quad Assembled Like Dipoles

Measured b_3 (octupole) $\neq 0$

Also seen in
80 mm Arc Quad
(7 unit in both
magnets)

A Simple Method For Removing Octupole From Quad

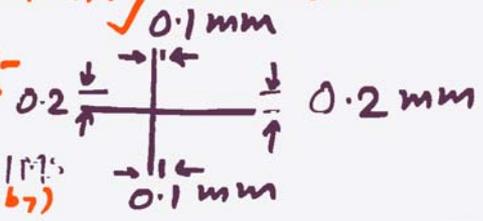

BASIC Problem

- (a) Trying to assemble quad like dipole
- or
- (b) Starting Yoke i.d. is circular (which becomes non-circular after assembly)

Fix

1. Start out-of-round yoke; so that when assembled, it is round
 → Too late for that (and too expensive to change)
2. Create deliberate asymmetry in coil to compensate for that

→ Easy, Tested and Worked
 AND/OR USE MAGNETIC TUNING SHIMS (b5 & b7)

Goals of End Design

Magnetic Design

- Optimize for low integrated harmonics
- Guide design towards lower peak field without large increase in length
- Compute cross talk and fringe fields

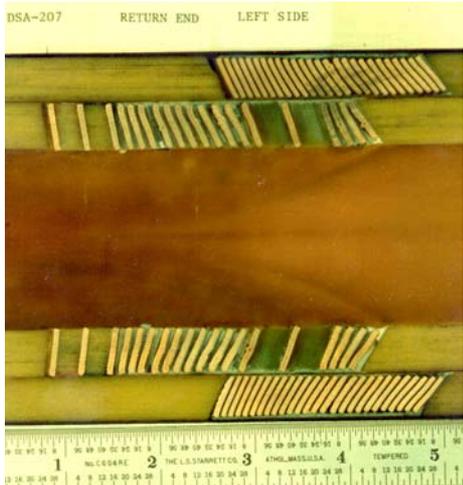

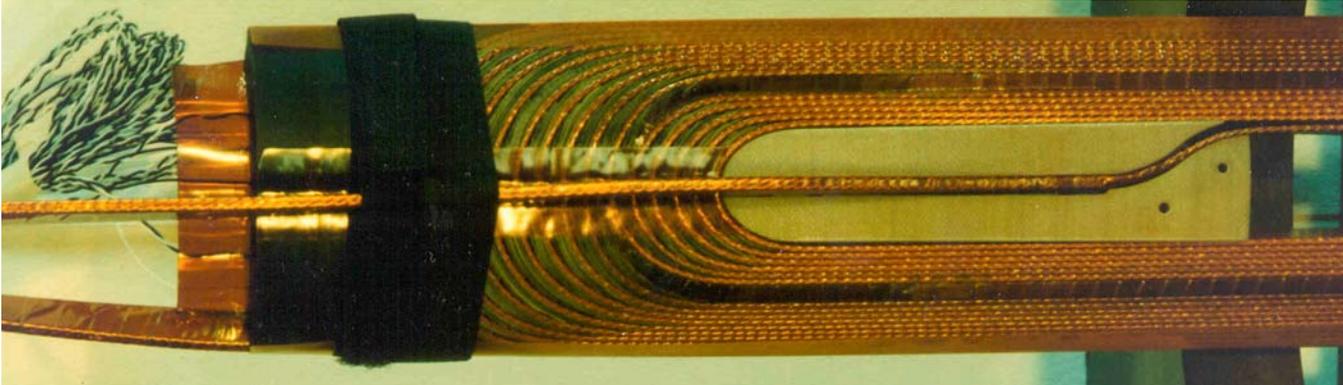

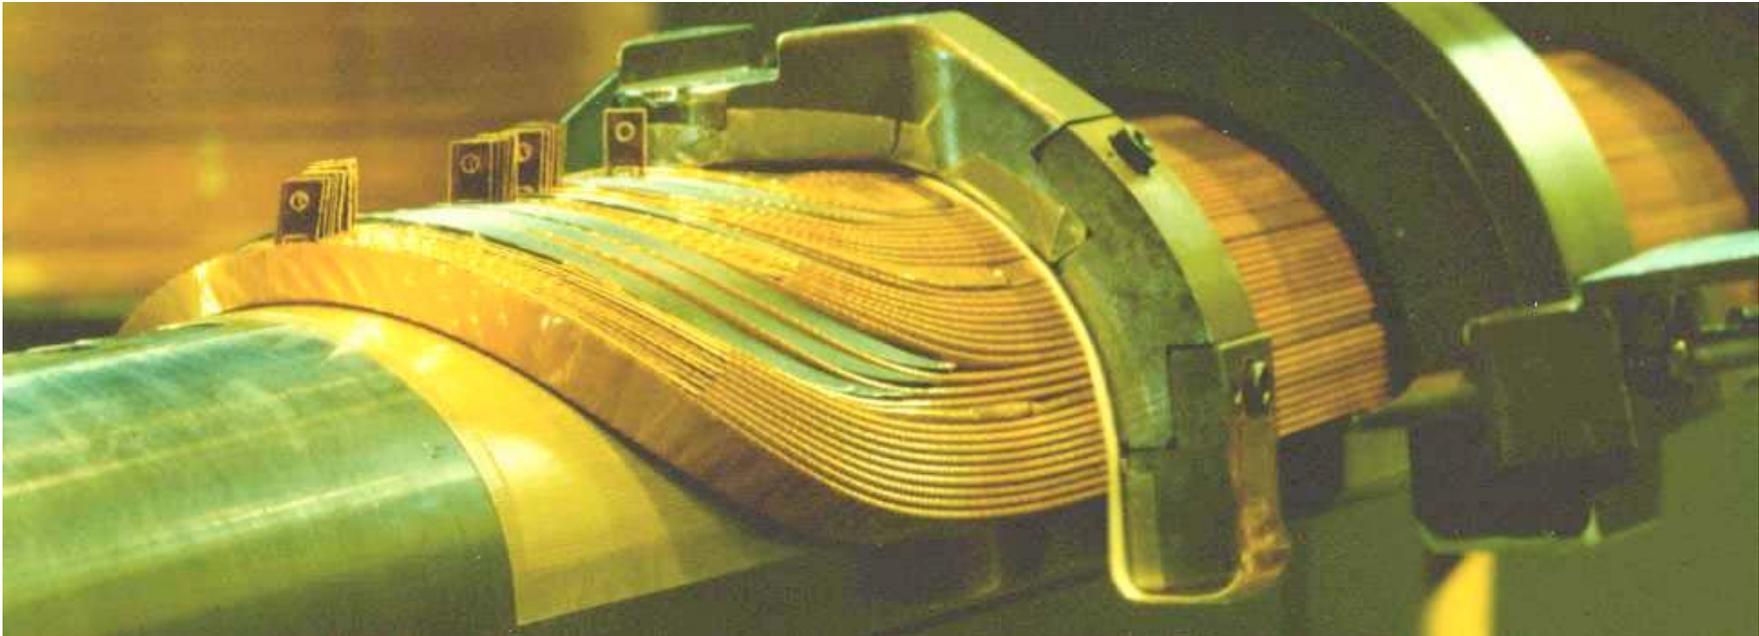

Mechanical Layout

- Minimize strain and tilt of the cable in the end. Minimize large changes
- Cable and entire ends should be well supported (constrained)

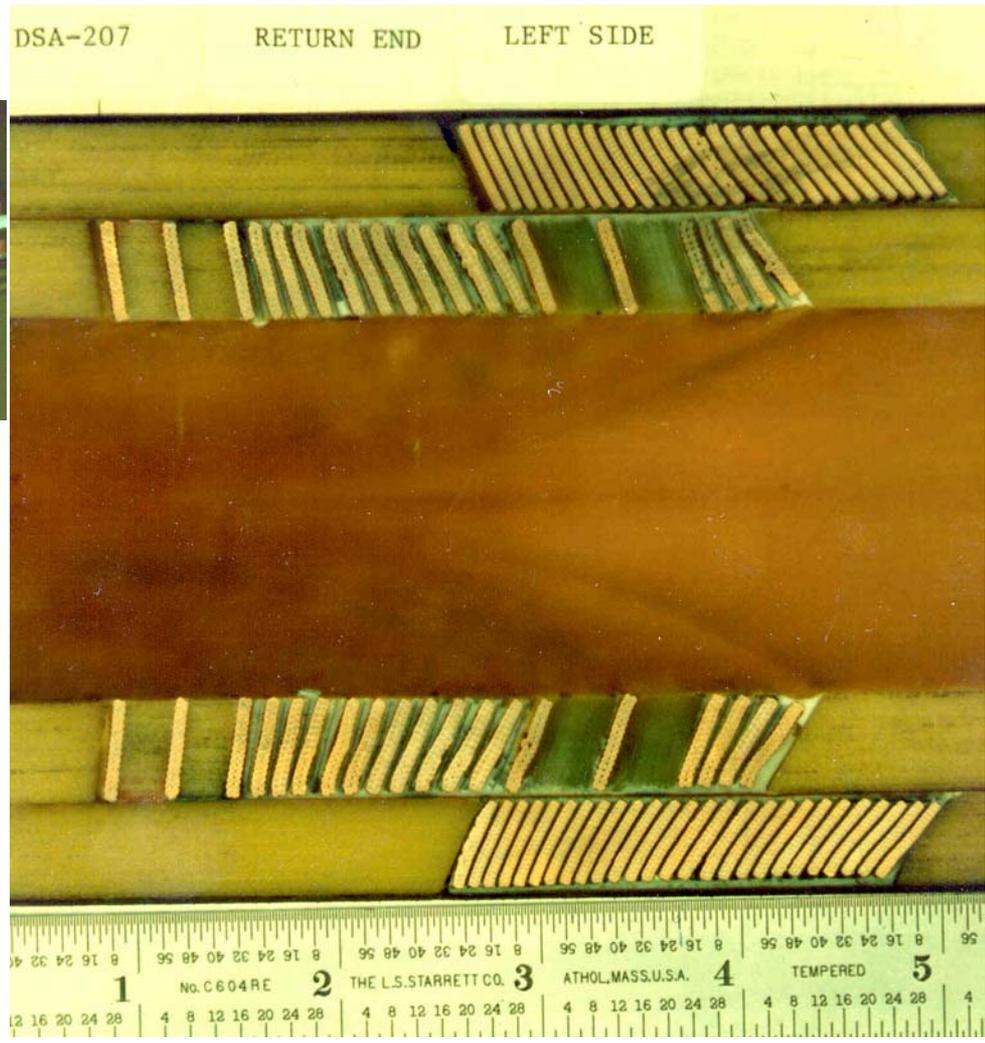

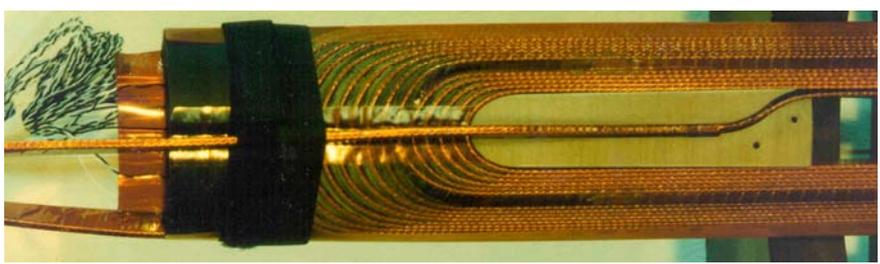

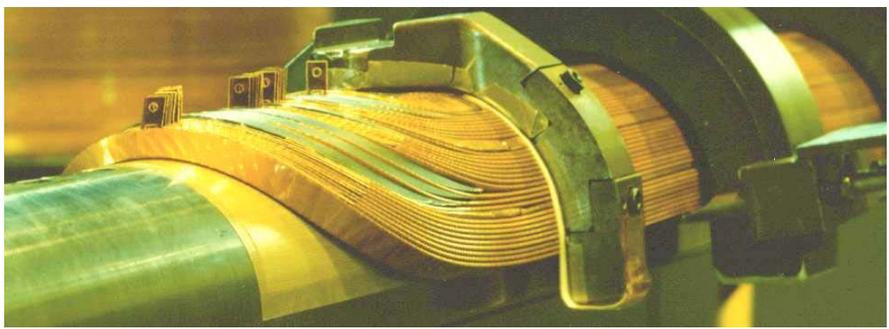

In low field magnets, magnetic design drives the end design, whereas, in high field (high force) magnets, the mechanical design must!

These guiding principle are common to our all high force magnet designs (including 12 T common coil dipole design).

Ends of Cosine Theta Cable Magnets

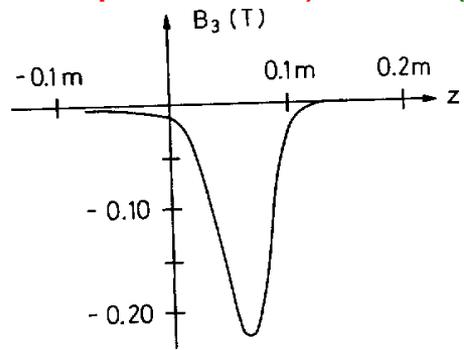

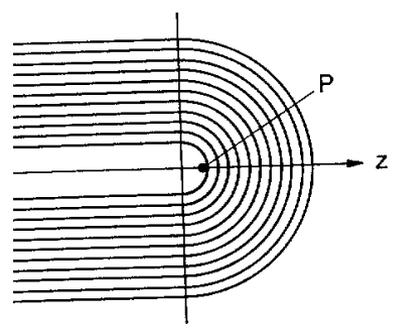

Ends of Cosine Theta Cable Magnets

End Harmonic Optimization (conceptual)

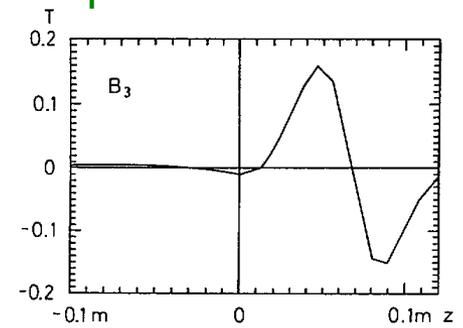

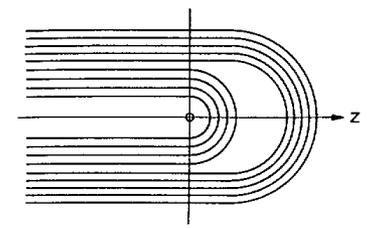

Ends without spacer

(large harmonics and peak field)

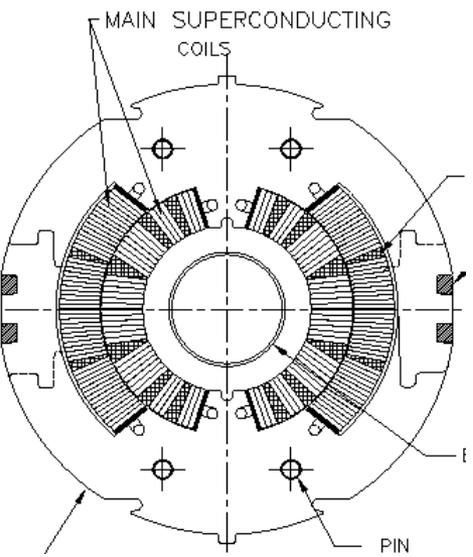

Ends with spacer

(integrated harmonics & peak field reduced)

a) Schematic view of HERA coil head with spacers

b) Computed sextupole field of HERA dipole

- End spacers increase the straight section length of some turns (turns at midplane go further out)
- Now consider the integral field generated by each turn. The harmonic component generated by a turn will depend on the angular location of it. The integral strength will depend on the length.
- A proper choice of end spacer can make integral end-harmonics small. However, note that the local values are large.
- Spacer also reduce the maximum value of field on the conductor (peak field) in the end.

Block Structure

Straight section (6 blocks, 70 turns):

30 20 10 4 3 3 (counting from midplane)

3 3 4 10 20 30 (counting from pole)

End section (8 blocks, 70 turns):

10 5 8 4 13 4 6 20

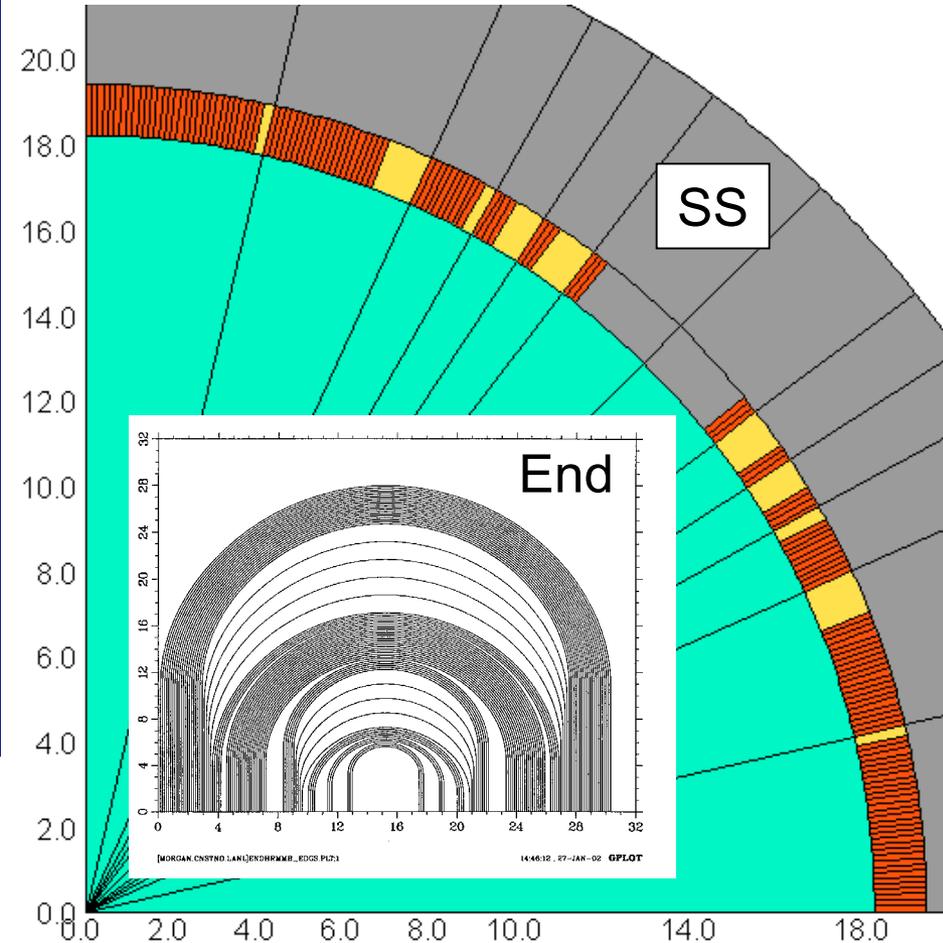

(counting from pole)

Straight section => pole

3,3,4 => 10

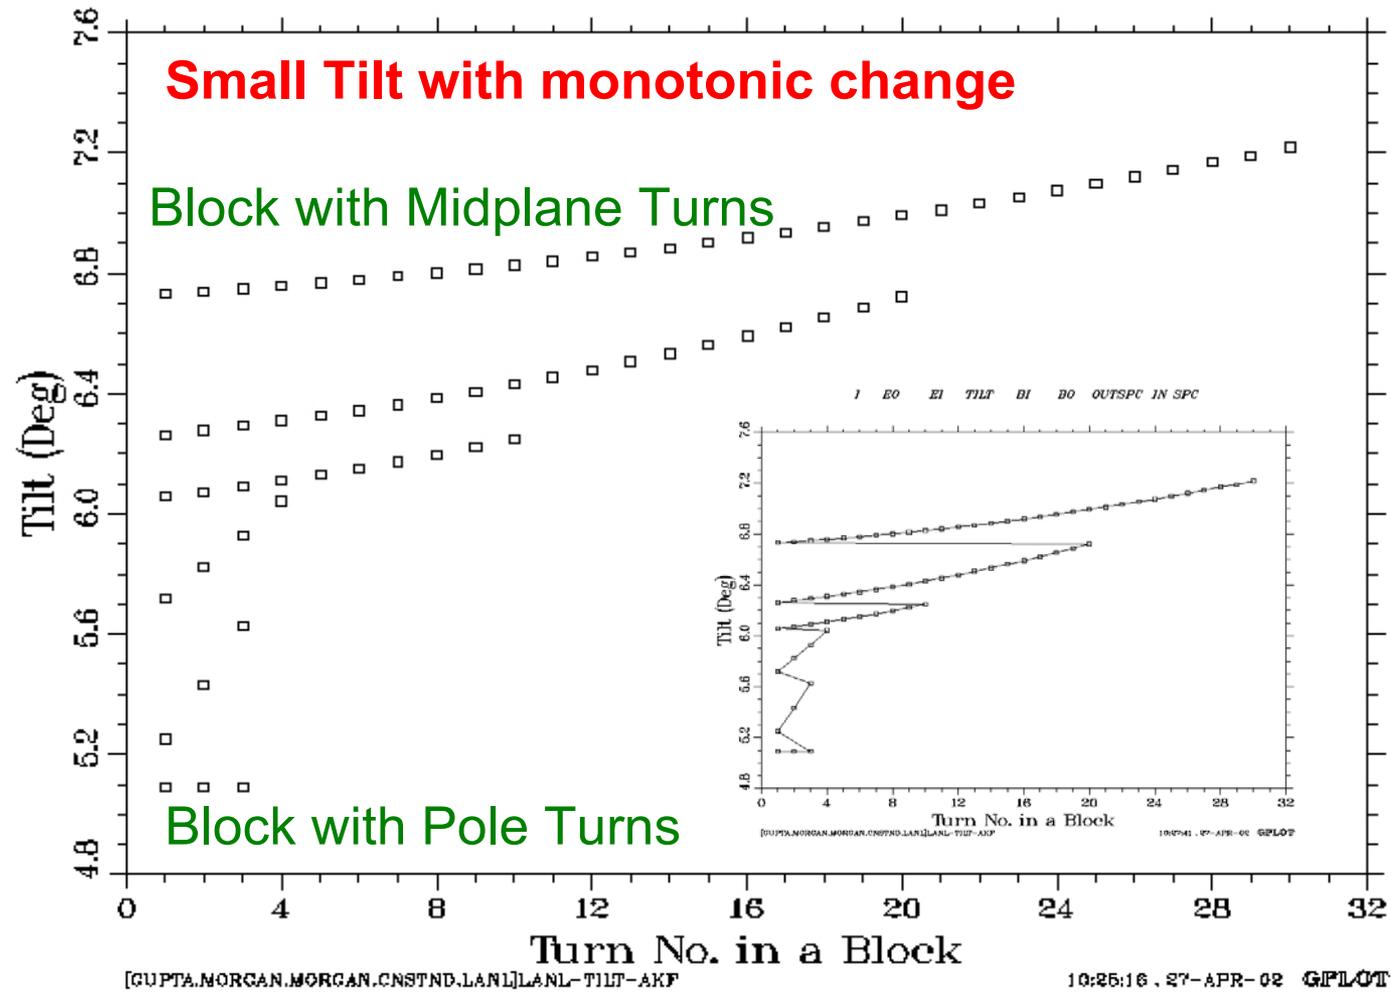

4,10, 20 => 5, 8, 4, 13

30 => 4, 6, 20

Equal spacing in “Red Color” blocks is used as harmonic optimization parameters

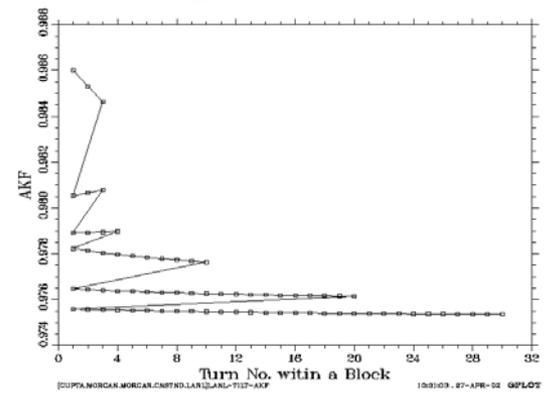

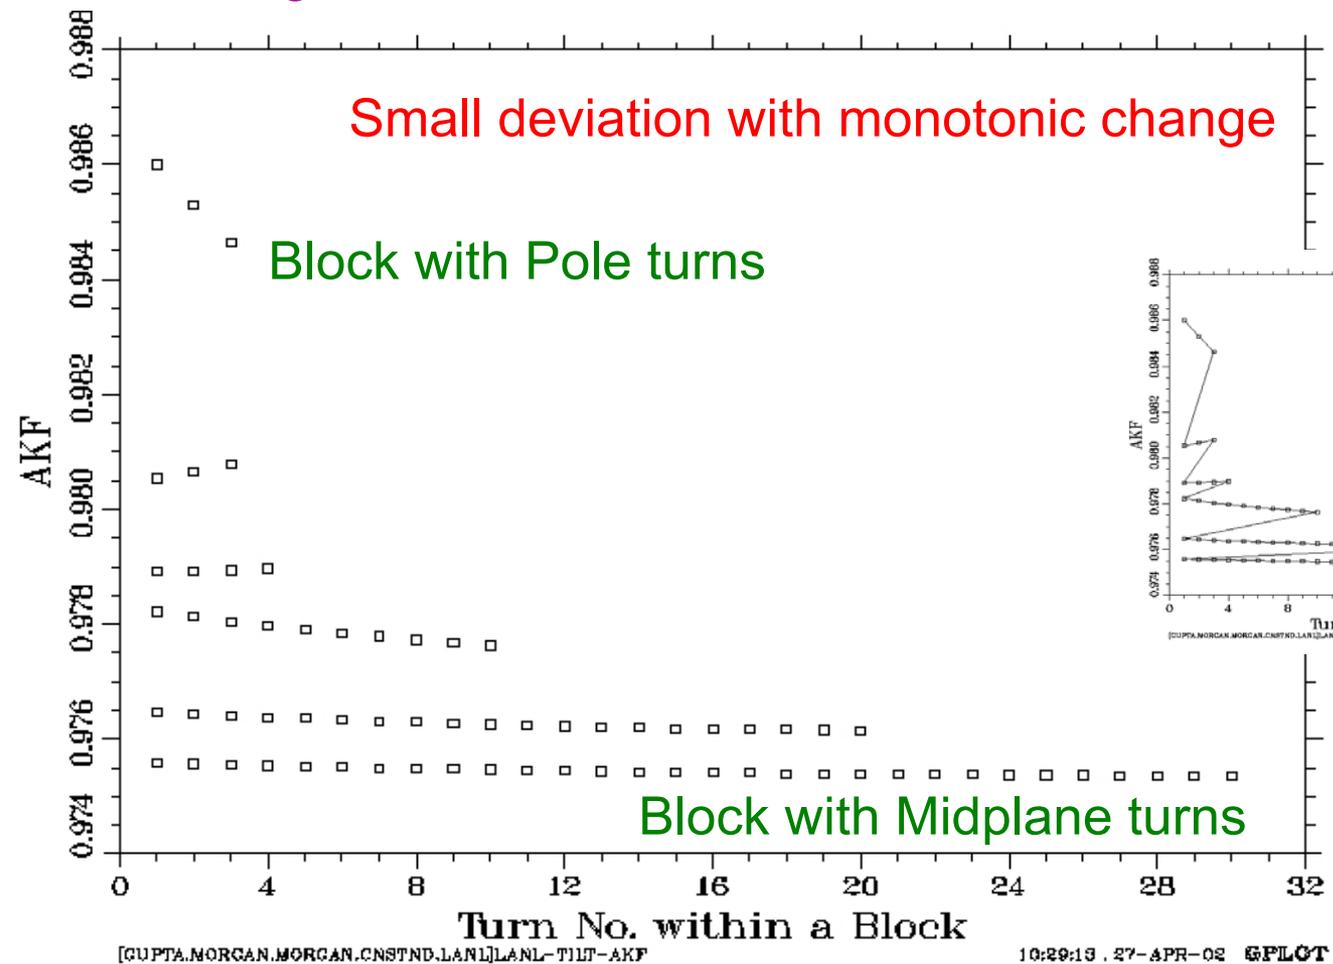

Tilt of Turns in Various End Blocks (at far out position)

The AKF Parameter of Turns in Various End Blocks

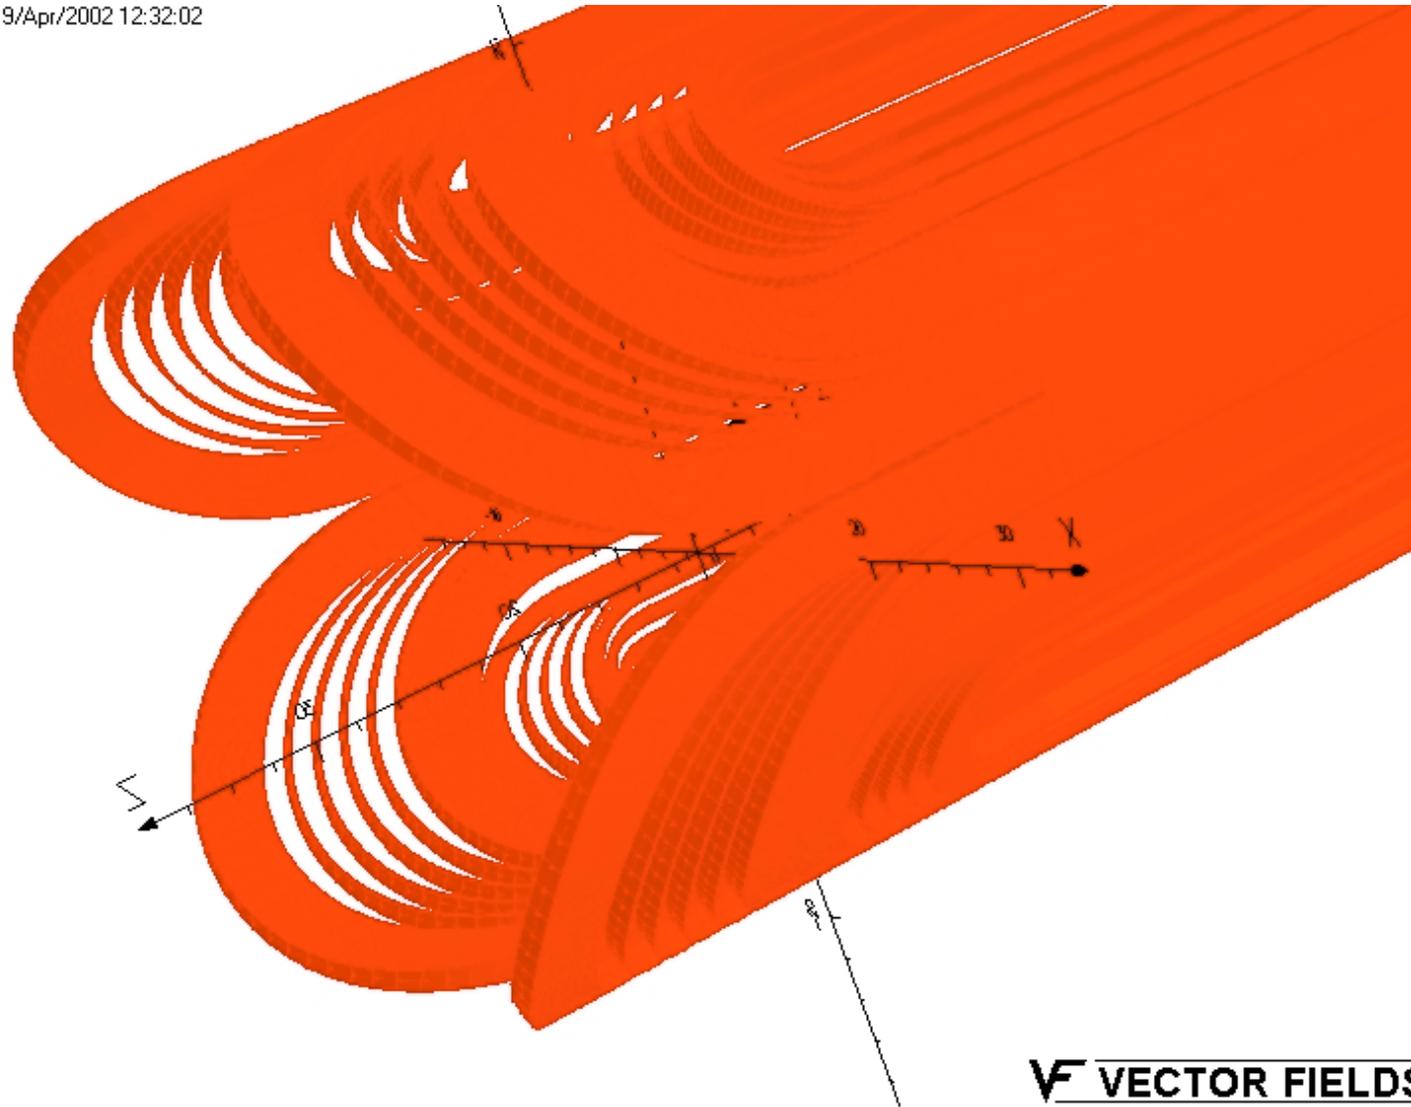

AKF indicates the deviation from constant perimeter (hence strain on the cable)

Large Deviation from 1.0 is bad

19/Apr/2002 12:32:02

Coil End: Design A

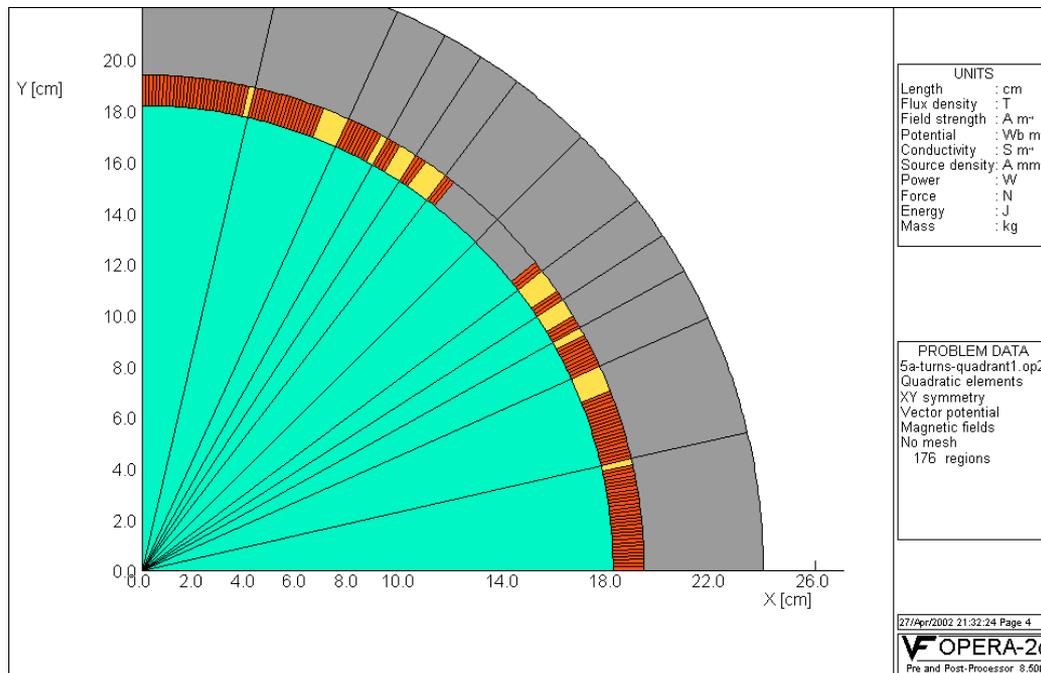

V VECTOR FIELDS

Peak Field Minimization

A high peak field reduces the magnet quench performance.

➤ **A large effort must be undertaken in 2-d optimization.**

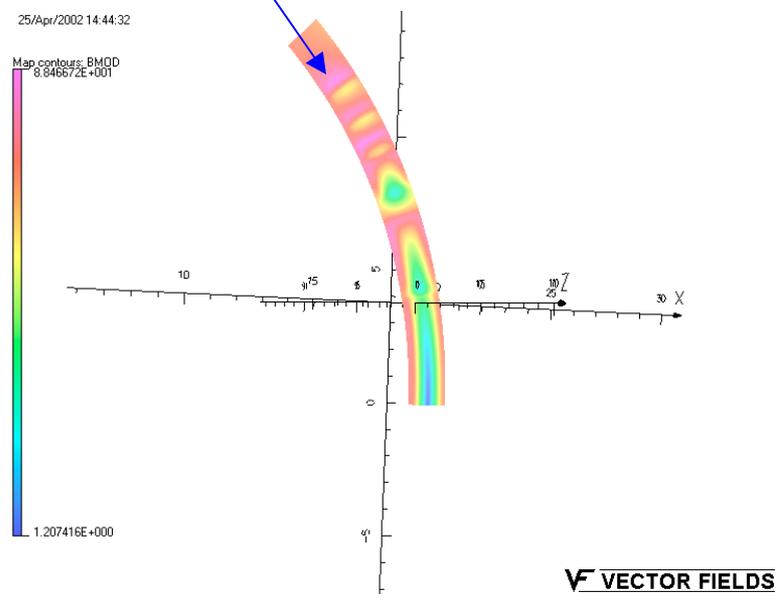

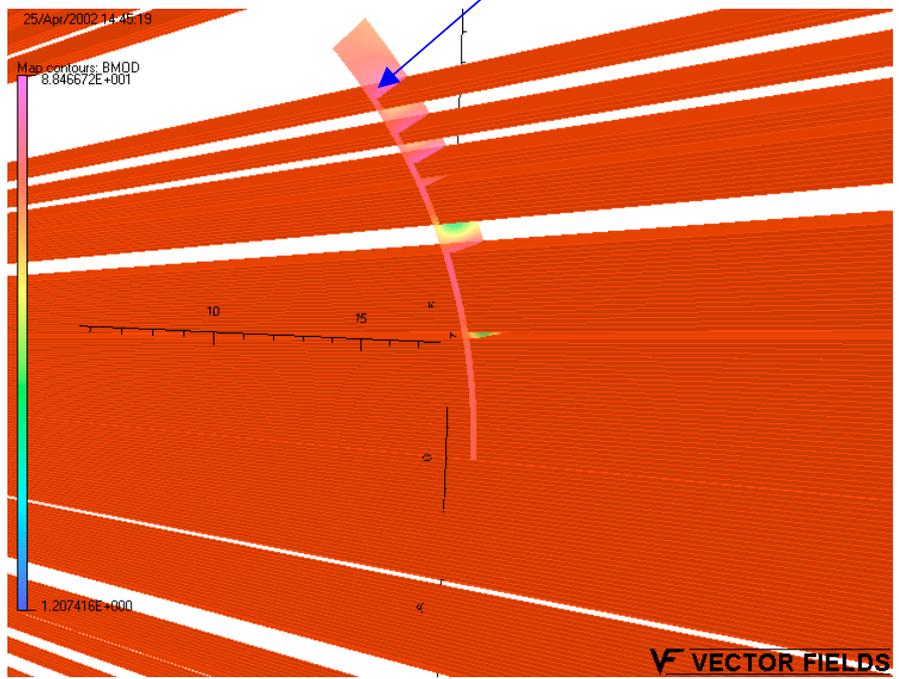

Usually about thousand cases are examined to :

- Minimize harmonics
- Find a solution with lower peak field
- Good mechanical turn configuration (wedges, tilt angle, etc).

A series of computer programs have been written to carry out the above optimization in an exhaustive and systematic manner.

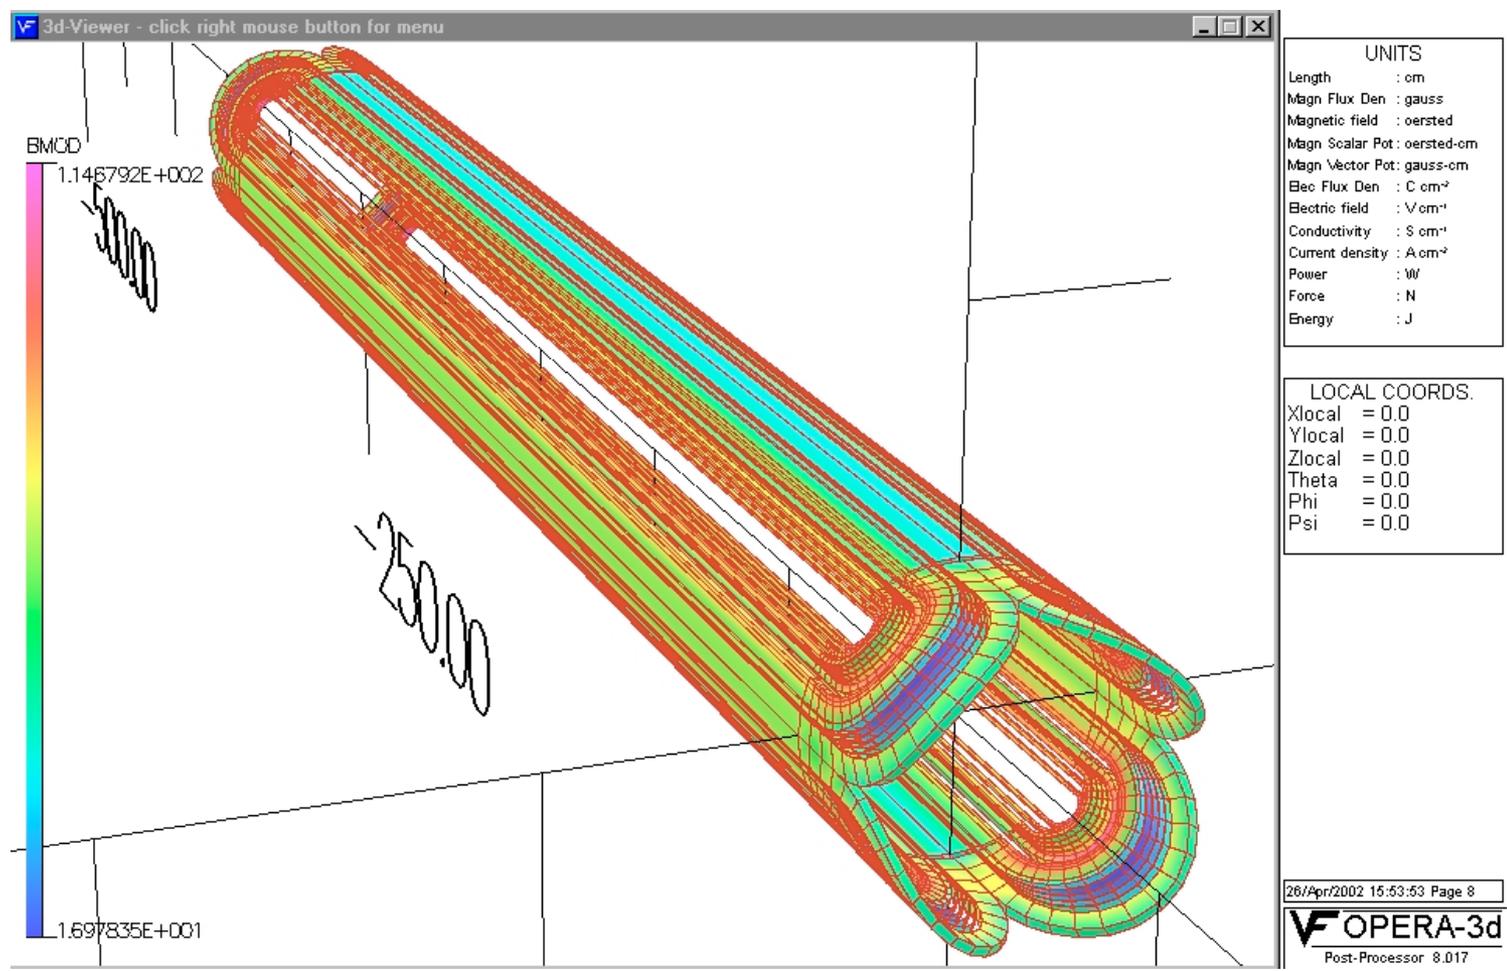

Peak Field in the Body of the Magnet

Peak Field Location (pole turn)

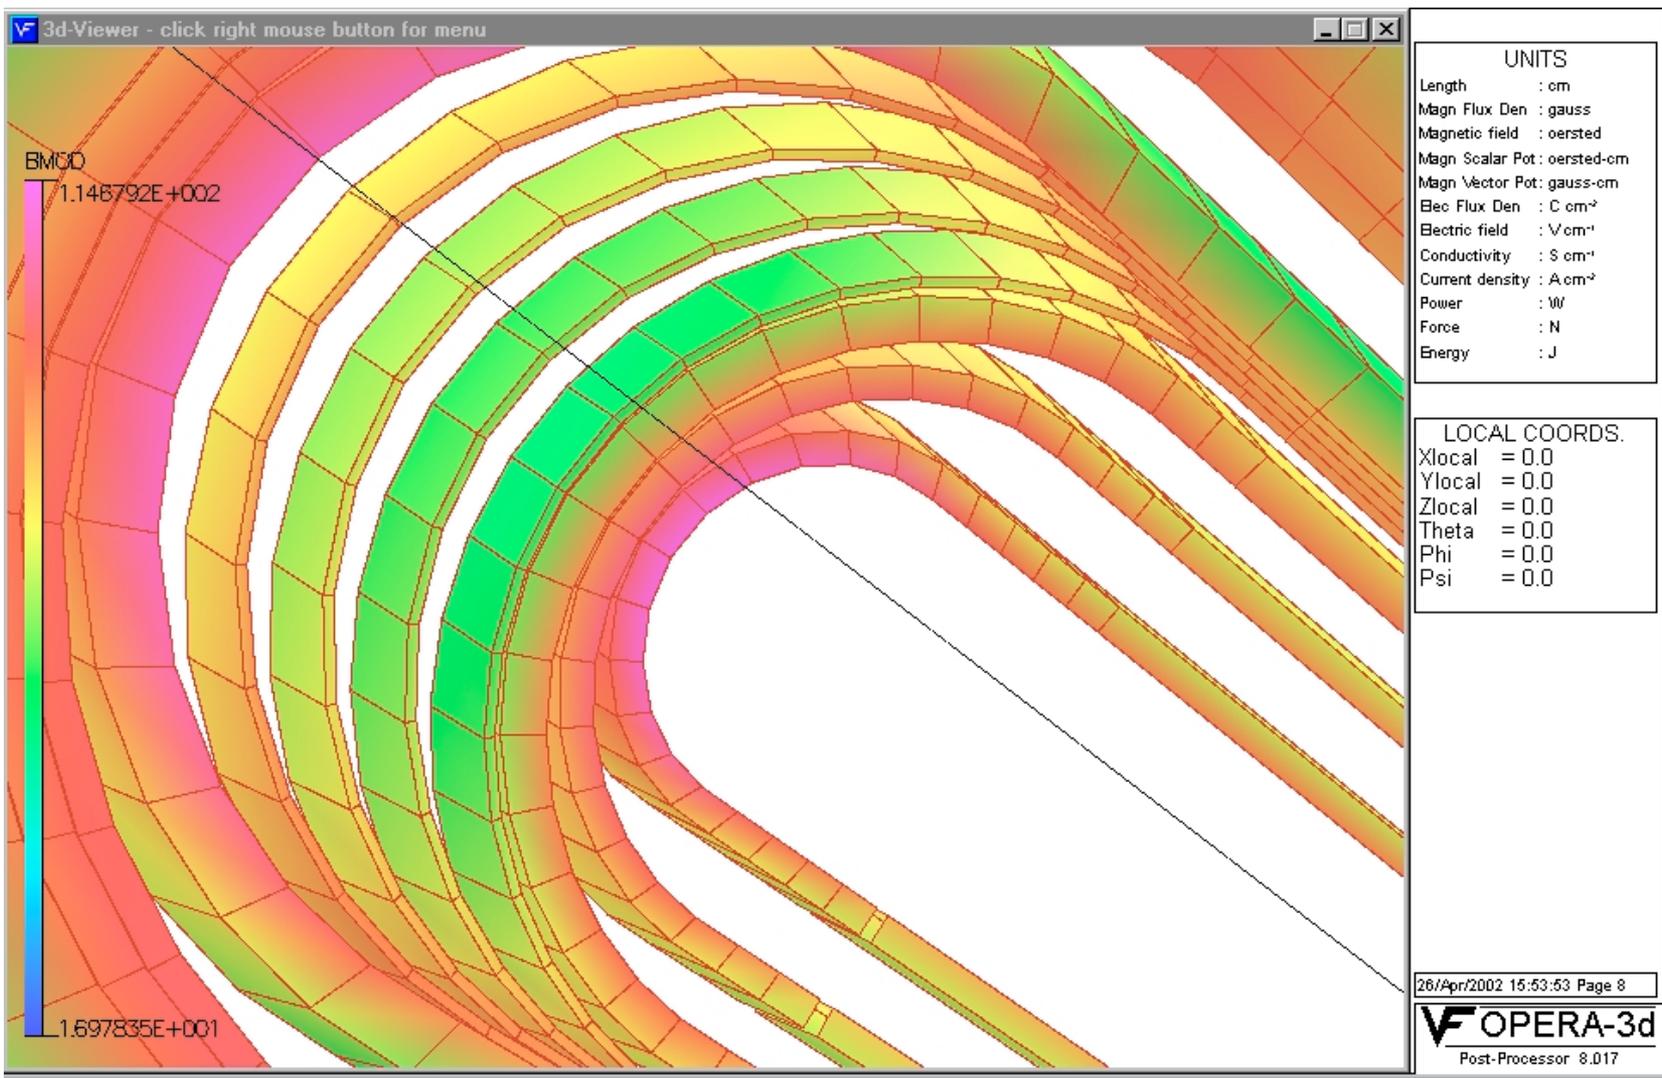

Peak Field in the End

An example of an End Design

Peak Field in the End

Peak Field in the Ends

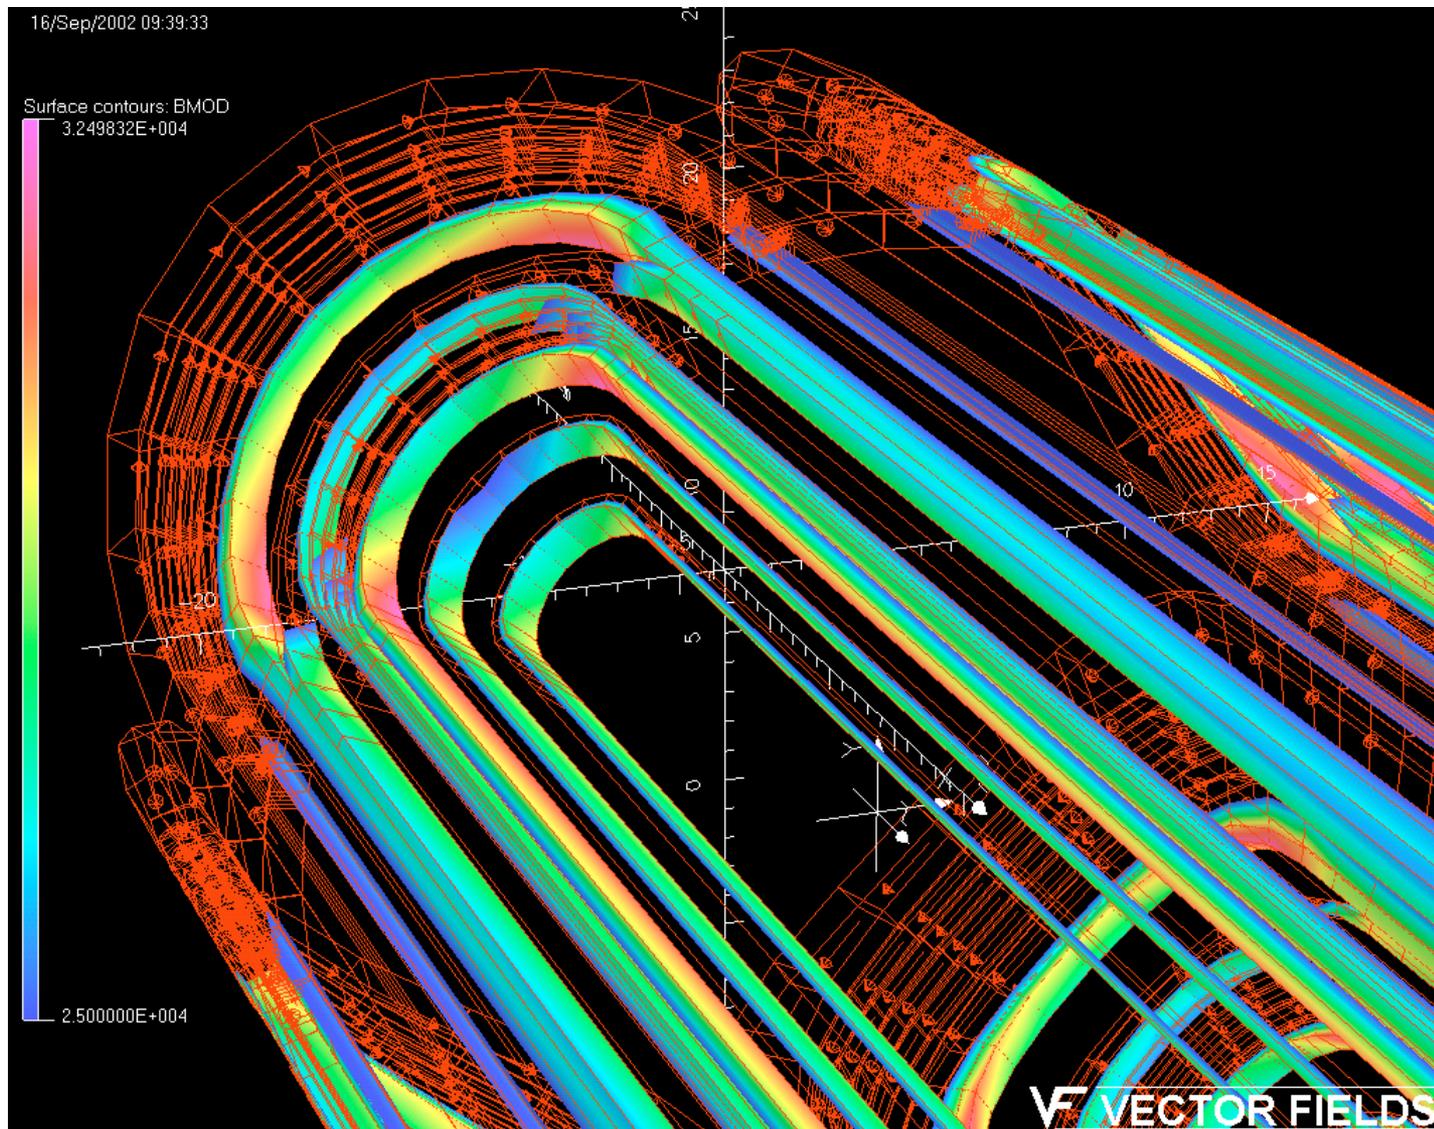

In cosine theta magnets, the conductors in the Ends are more strained and the mechanical design is generally less robust.

Therefore, one would like the peak field in the Ends to be less than that in the body of the magnet, to give conductor a larger margin.

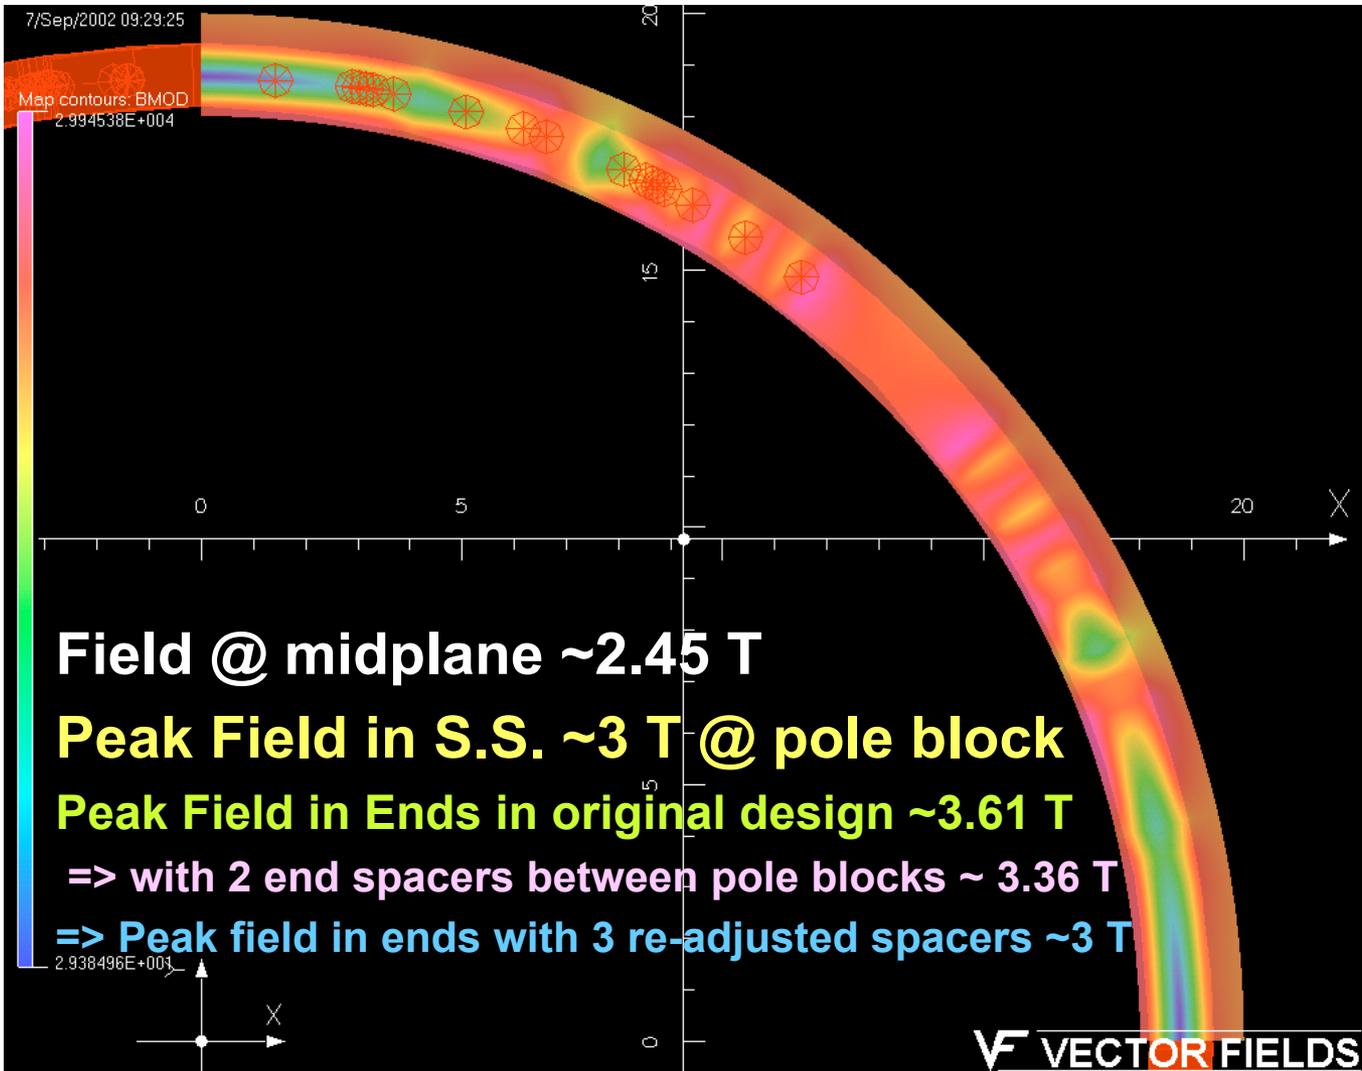

Ends with 3 Re-adjusted Spacers

Example
(optimized):

Re-adjusted
end spacer
brings field in
the ends down
to S.S. level.

Peak Field Straight Section vs. Ends

Block Structure

Superconducting
Magnet Division

Straight section (6 blocks, 70 turns):

30 20 10 4 3 3 (counting from midplane)

3 3 4 10 20 30 (counting from pole)

End section (8 blocks, 70 turns):

10 5 8 4 13 4 6 20

(counting from pole)

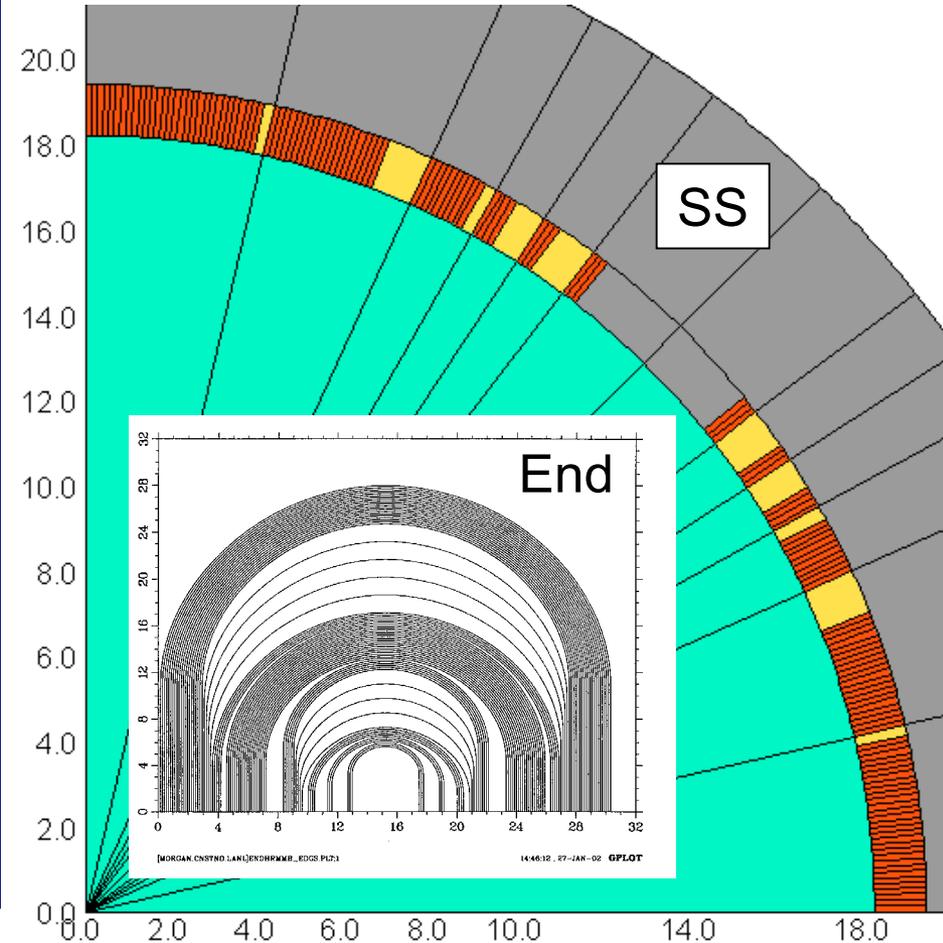

Straight section => pole

3,3,4 => 10

4,10, 20 => 5, 8, 4, 13

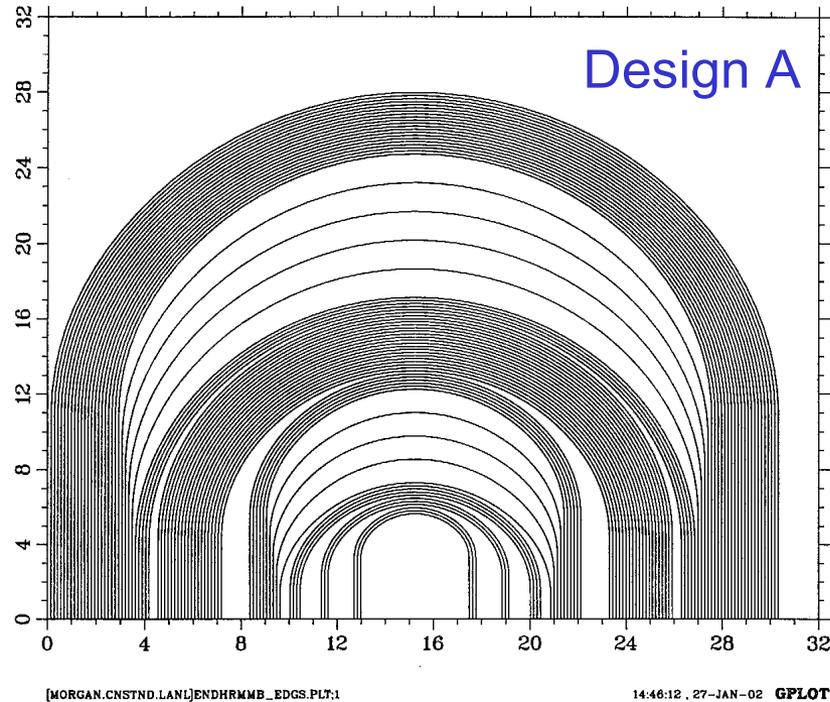

30 => 4, 6, 20

Must avoid large Ultum spacers
(subdivide, if necessary)

Equal spacing in "Red Color" blocks is used as harmonic optimization parameters

End Harmonic Optimization: SMINSQ

Parameters optimized:

End spacers in block #2 (with 5 turns) and end spacer in block #7 (with 4 turns).

All spacers within a block have the same size.

Changing the size of two groups of end spacers was adequate to get all harmonics small.

Computed values:

$B_5 < 1$ unit-meter;

B_9 and $B_{13} < 0.1$ unit-m

Effective Magnetic Length ~ 15.6 cm

Mechanical Length ~ 28 cm + End Saddle

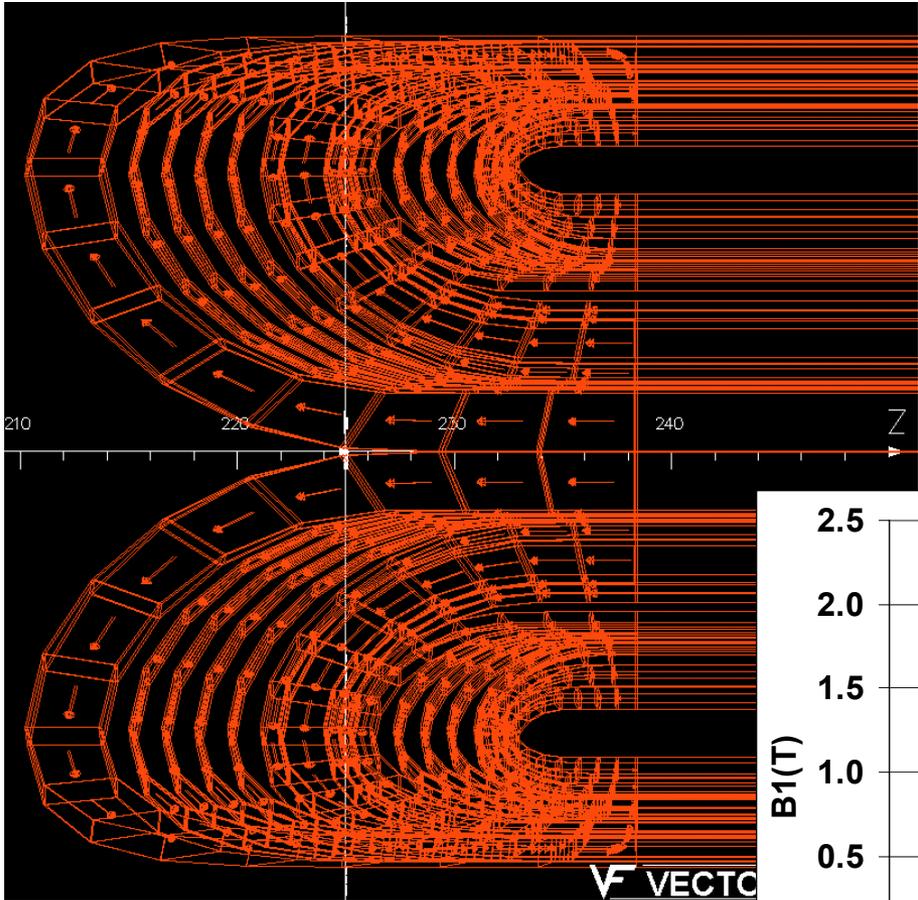

Block configuration:

(8 blocks, 70 turns):

10, 5, 8, 4, 13, 4, 6, 20

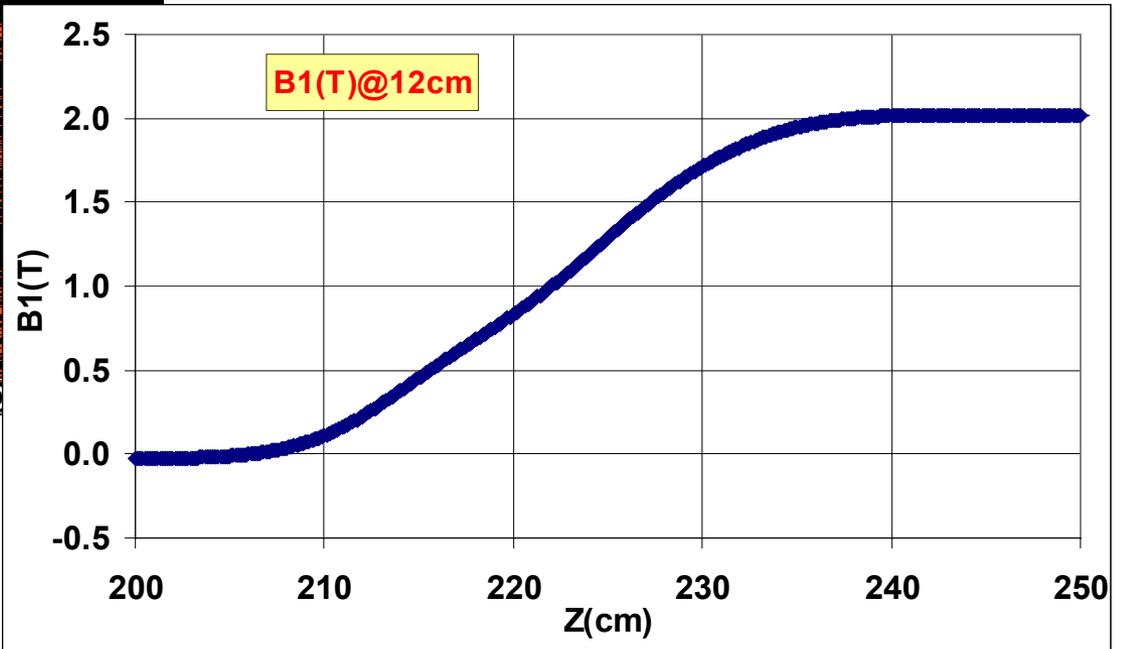

(counting from pole)

Field through the Coil Ends

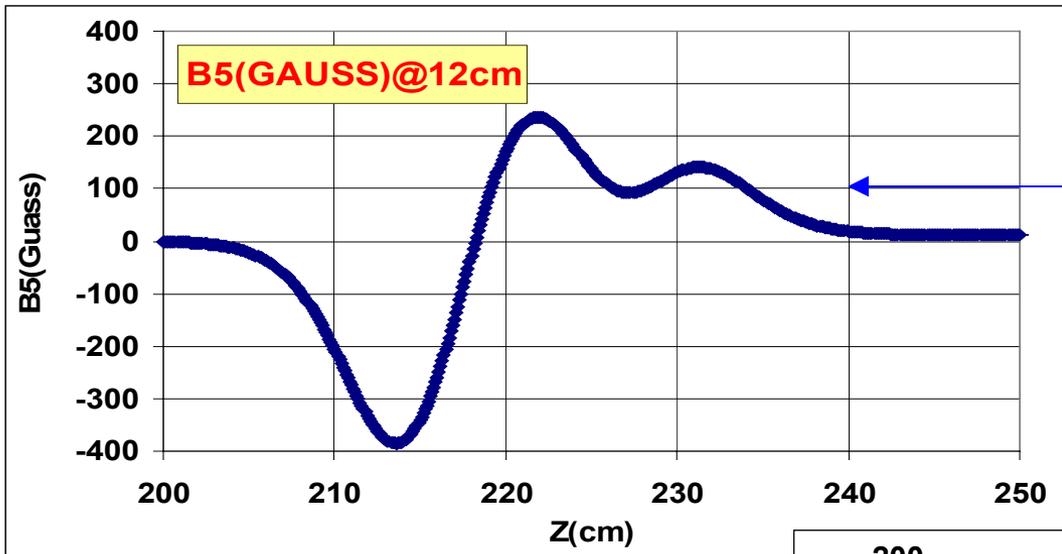

Mechanical length of this end (including end saddle) ~34 cm : ~ 2 coil diameters

Contribution to magnetic length ~16 cm

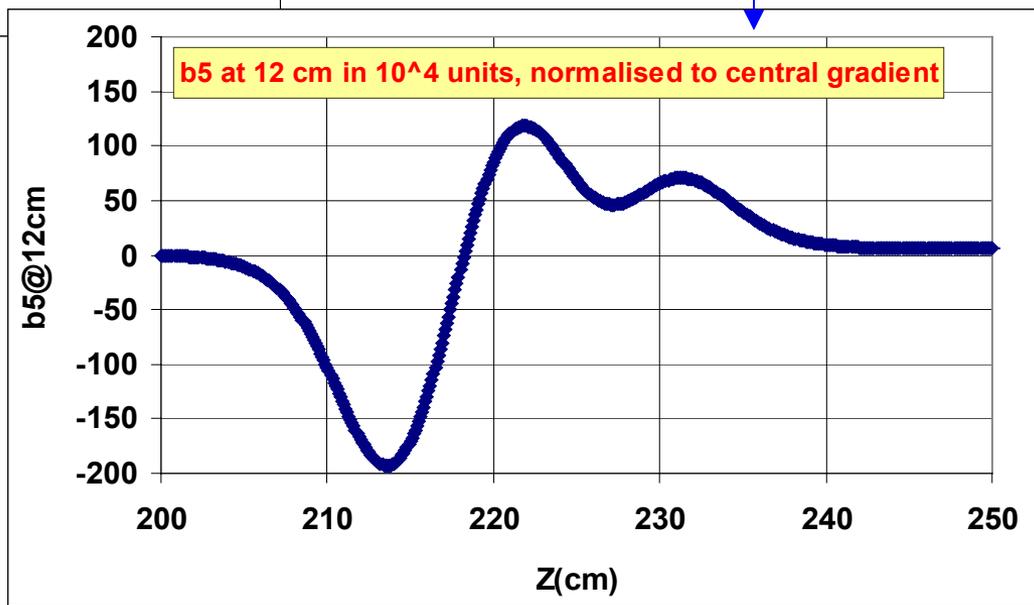

Field Harmonics through the End

b_5 : dodecapole

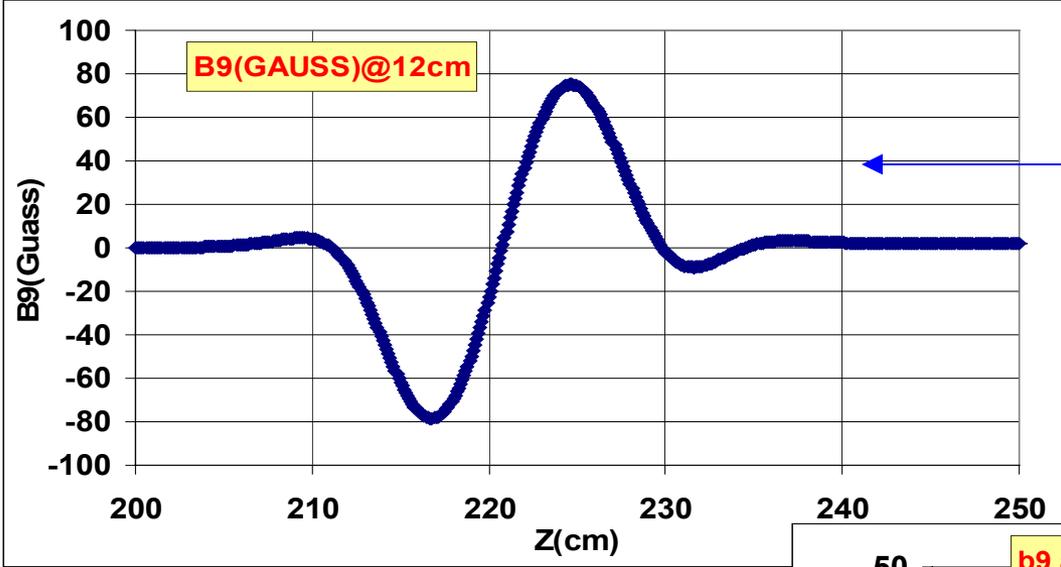

Harmonic in Gauss

Harmonic in Units

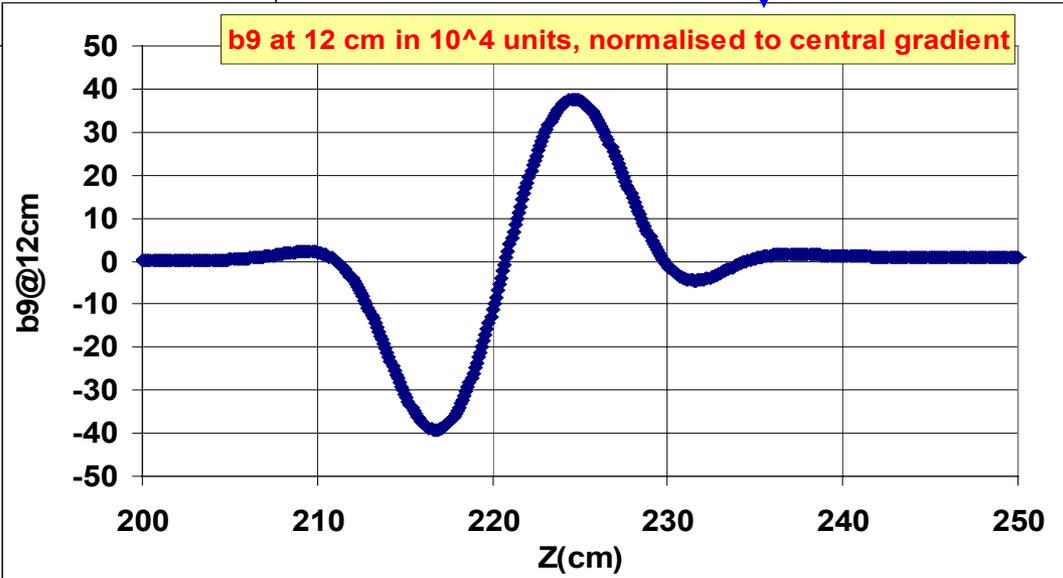

End spacers are optimized to produce low integral harmonics

Field Harmonics through the End : b_9

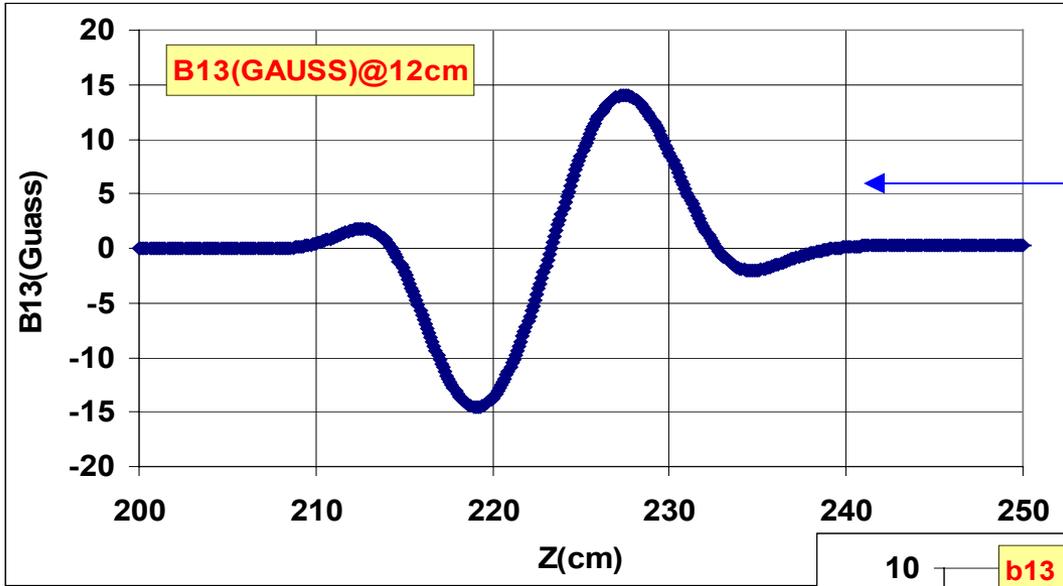

Harmonic in Gauss

Harmonic in Units

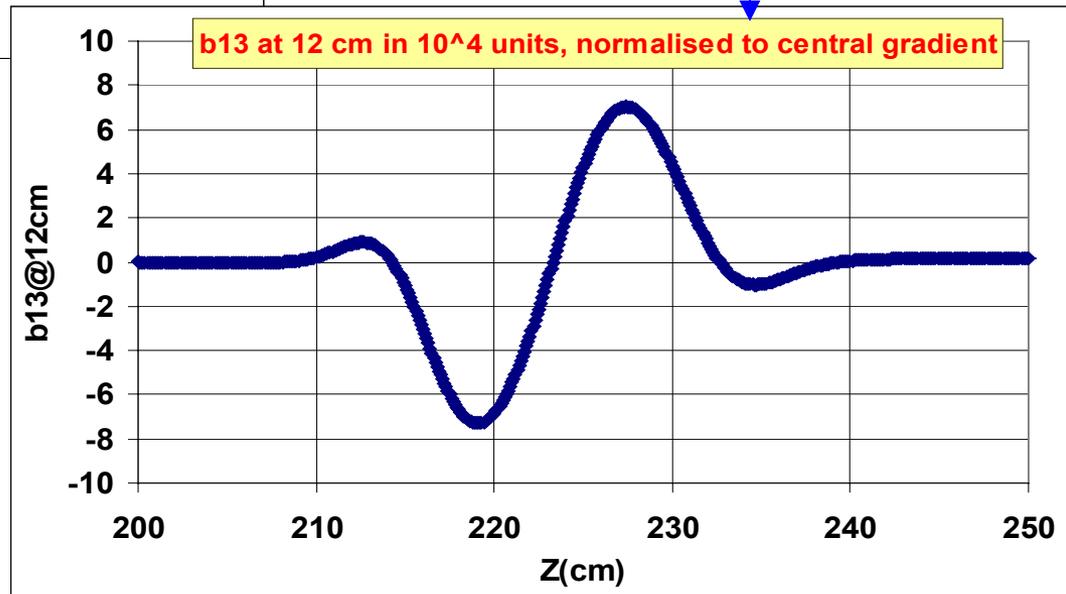

End spacers are optimized to produce low integral harmonics

Field Harmonics through the End : b_{13}

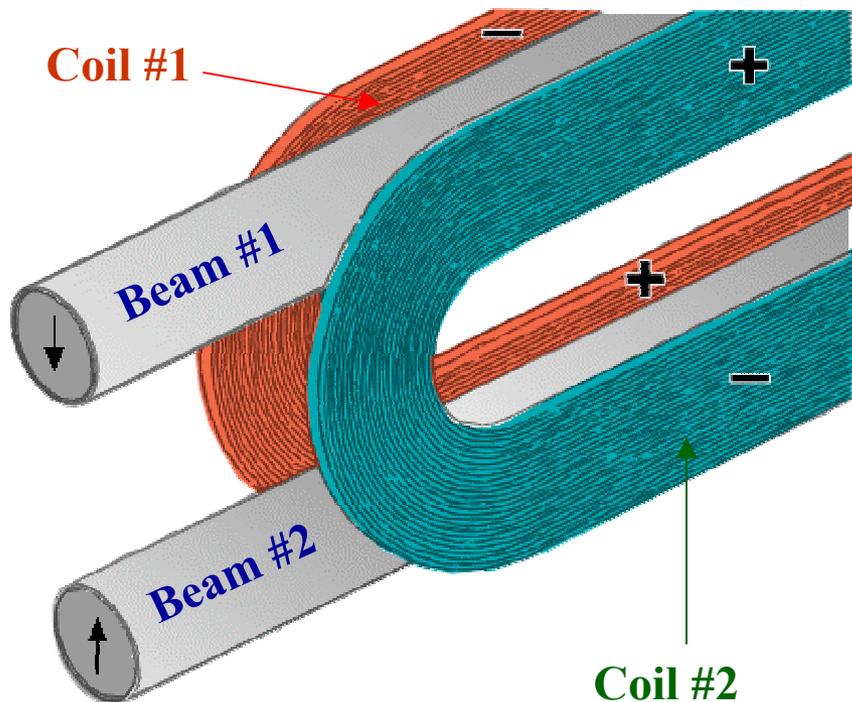

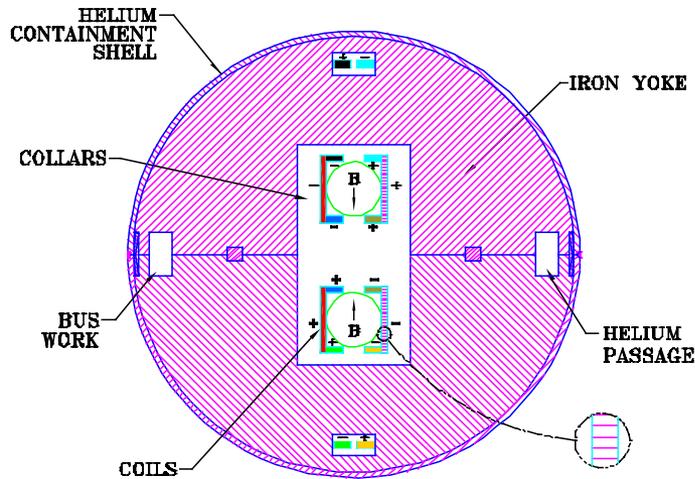

Harmonic in Gauss

Harmonic in Units

End spacers are optimized to produce low integral harmonics

Common Coil Design (The Basic Concept)

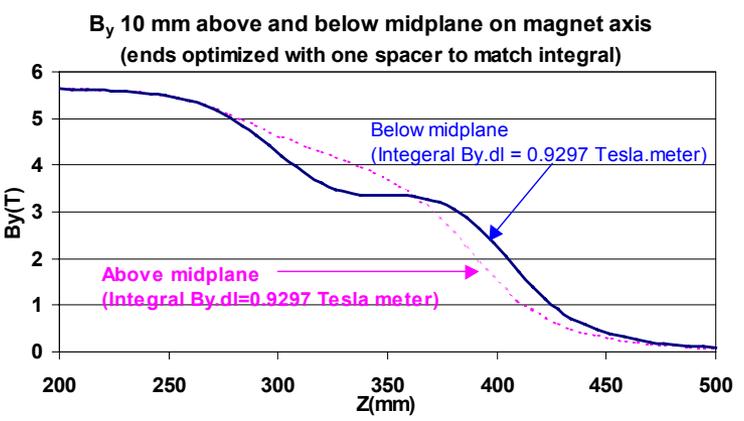

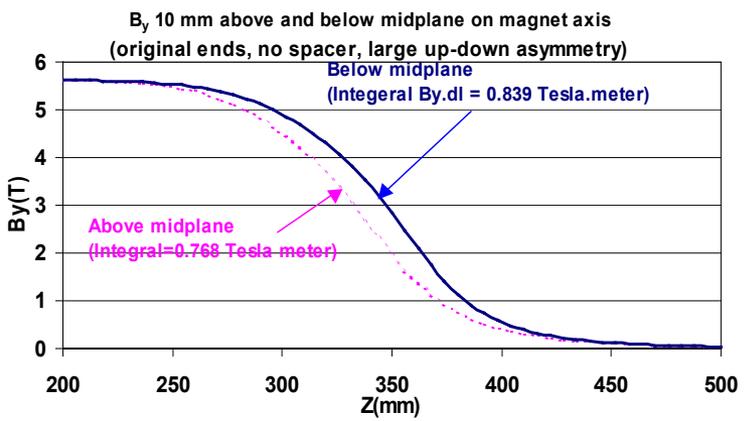

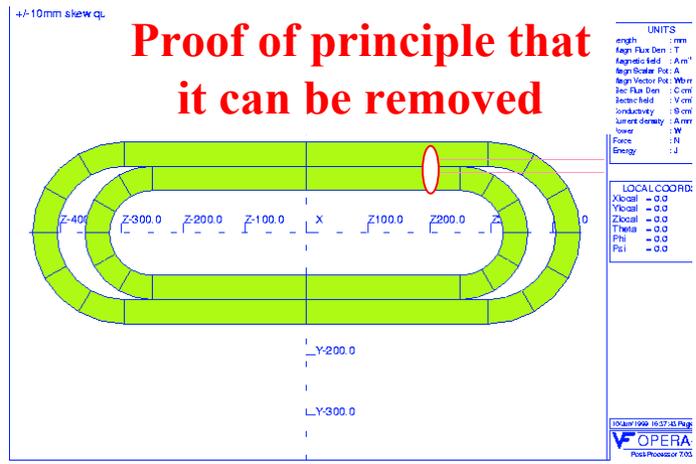

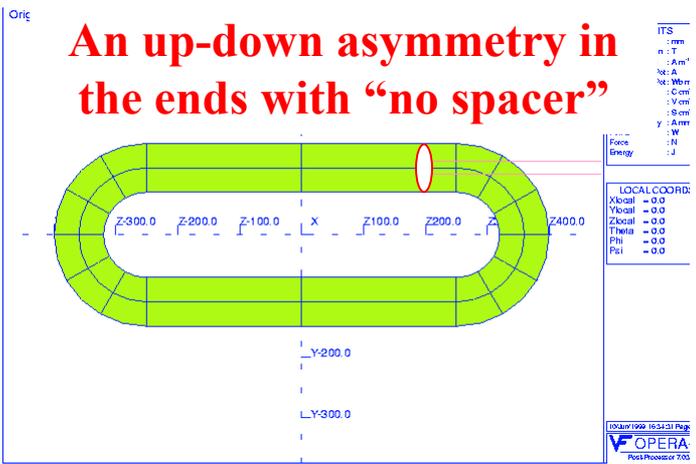

Main Coils of the Common Coil Design

- **Simple 2-d geometry** with large bend radius (no complex 3-d ends)
- **Conductor friendly** (suitable for brittle materials - most are - Nb_3Sn , HTS tapes and HTS cables)
- **Compact** (compared to single aperture LBL's D20 magnet, half the yoke size for two apertures)
- **Block design** (for large Lorentz forces at high fields)
- **Efficient and methodical R&D** due to simple & modular design
- **Minimum requirements** on big expensive tooling and labor
- **Lower cost magnets** expected

Field Quality Optimization in the Common Coil Design (Magnet Ends)

Up-down asymmetry gives large skew harmonics, if done nothing. Integrate $B_y.dl$ 10 mm above and 10 mm below midplane.

Up-down asymmetry can be compensated with end spacers. One spacer is used below to match integral $B_y.dl$ 10 mm above & below midplane.

A large $B_z.dl$ in two ends (~1 T.m in 15 T magnet).

- Is it a problem?
- Examine AP issues.
- Zero integral.
- Lead end of one magnet + Return of the next magnet will make it cancel in about ~1meter (cell length ~200 meters).
- Small $v \times B$.

An Example of End Optimization with ROXIE (iron not included)

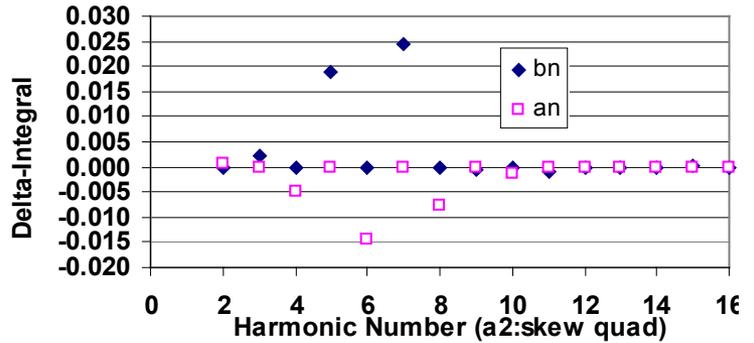

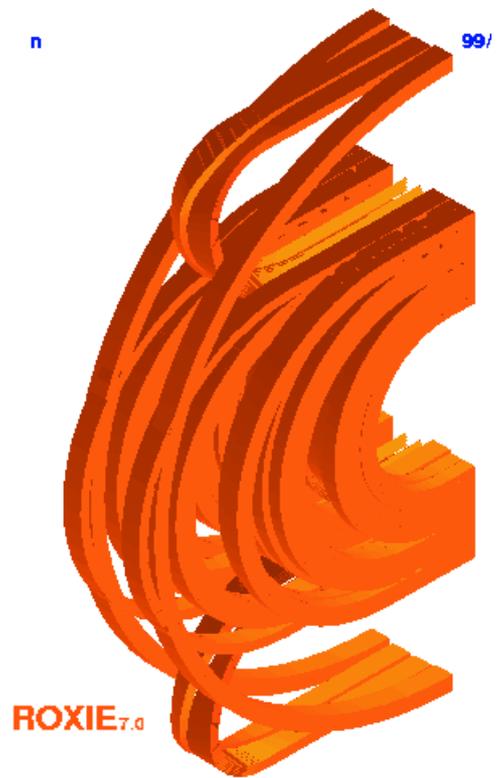

End harmonics can be made small in a common coil design.

Contribution to integral (a_n, b_n) in a 14 m long dipole ($<10^{-6}$)

Reduction in Peak Field in the Ends of Common Coil

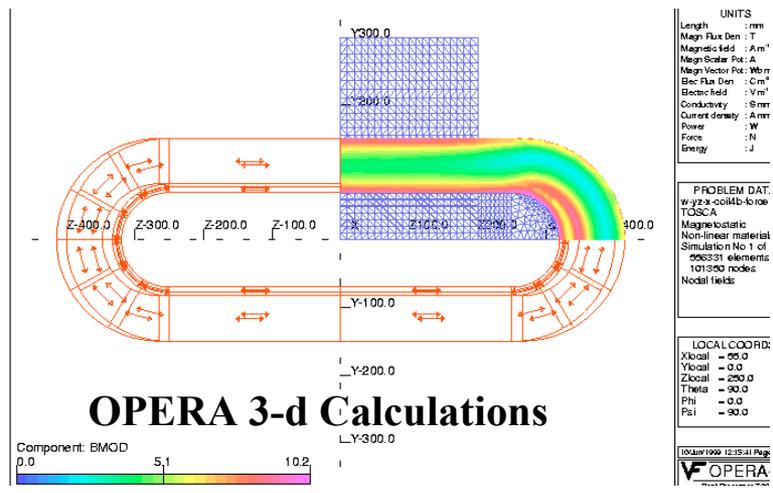

Peak field in the ends is minimized by:

- Removing iron over the ends

Field and Field lines as computed by OPERA 2-d

Peak field in the outer layer

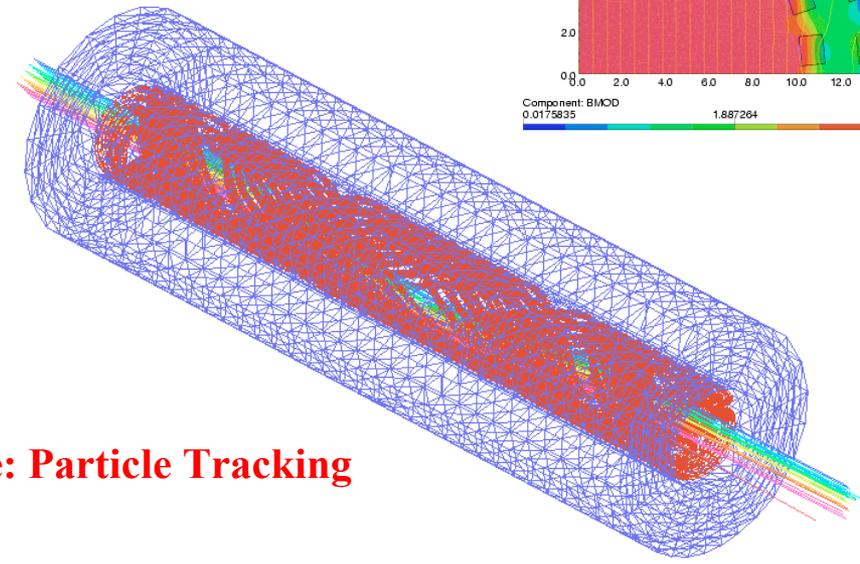

- Using end spacers between the turns.

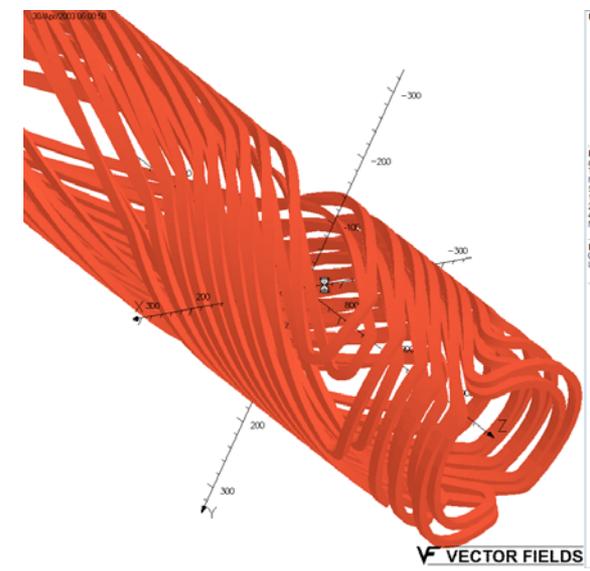

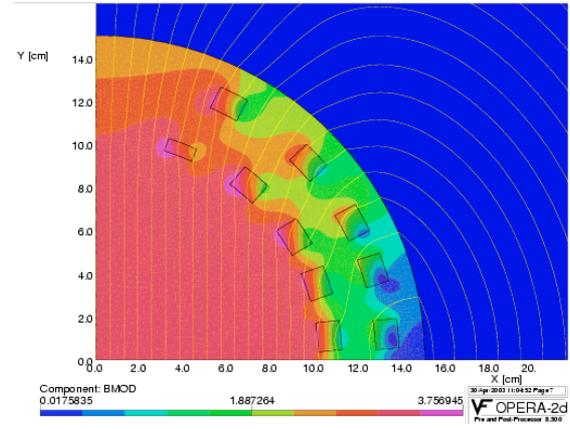

A Helical Magnet for AGS at BNL (1)

Superconducting Magnet Division

This magnet uses helical coils to maintain the polarization of the beam as it passes spin resonances in AGS.
